Since 1900, the US Census Bureau has regarded as 'incorporated places' only municipalities incorporated as cities, boroughs, or villages, and towns except in New England, New York, and Wisconsin. While not questioning that the towns in the latter states are incorporated municipalities, the census does not regard them as places, because they typically include much open country as well as population concentrations.

Township governments are also especially strong in New Jersey, Pennsylvania, Michigan, and Minnesota. In all 12 strong-township states, recent censuses have provided much the same range of data for towns and townships as for incorporated places of comparable size. Most of the other Midwestern states also have subdivisions termed townships, as do Arkansas and North Carolina, but their municipal activities are few or nonexistent today. The Census Bureau treats them like the MCDs of other states (U.S. Bureau of the Census, 1994: Chapter 8; U.S. Census Bureau, 2012: Table 39).

New England Towns: Urban or Rural?

The existence of these town-type municipalities in New England and other states not surprisingly has created problems of comparability for an urban category defined in terms of municipalities of a specified size. Under the varying rules of the censuses prior to 1930, all or most New England towns that met the population threshold were included as wholly urban.

In 1930, an adjustment was made under which only towns in Massachusetts, New Hampshire, and Rhode Island could qualify, provided they contained "a village or other thickly settled area having more than 2500 inhabitants and comprising, either by itself or when combined with other villages in the same town, more than 50 percent of the total population of the town" (Truesdell, 1949: p. 9). However, in these cases, it was still the whole town that was treated as urban, not just the thickly settled portion.

Also in 1930 and 1940, a few political subdivisions in other states, regarded as analogous to the New England towns, were treated as urban under a special rule if they had at least 10 000 residents, a population density of at least 1000 per square mile, and included no subordinate incorporated place. Most of these special-rule areas were suburban in character and located in states with strong town or township governments. However, at that time the urban category still excluded extensive suburban development located in 'unincorporated' areas outside municipal boundaries.

Before the 1940 census, totals of urban population using the 2500 threshold were determined all the way back to the first US census in 1790. Towns in New Hampshire, Massachusetts, and Rhode Island were included for census years in which they appeared to meet the criteria adopted in 1930. The special-rule areas in other states were included only for 1940 and 1930.

The remainder of the population was defined as rural. With minor revisions and the addition of data for 1950 determined on the 1940 basis, these urban and rural totals for 1790 to 1950 based on places of at least 2500 have been published in each subsequent census (U.S. Census Bureau, 2012: Table 7).

Urbanized Areas

As early as 1790, urban development overflowed across some municipal boundaries, notably around Philadelphia. If the overflow was either annexed by the parent city or separately incorporated in places meeting the population threshold, it qualified to be included in the official urban category. However, by about 1900, annexation activity by large cities had slowed and a significant share of suburban development was taking place in unincorporated territory (Weber, 1899/1967).

The census responded to such changes from 1910 through 1940 by defining 'metropolitan districts,' which represented a functional approach not limited to the continuously built-up environs of cities. The next section of this article discusses them further.

The 1950 census introduced the concept of the UA, with the stated aim of providing a better separation of urban and rural populations in the vicinity of larger cities. A UA was defined to comprise at least one city of at least 50 000 and its more or less contiguous built-up suburbs, incorporated or unincorporated. Incorporated places were never split by a UA boundary, but in New England towns, suburban townships, and unincorporated territory generally only the built-up parts were included.

The 1950 UAs were defined using precensus fieldwork and a density criterion of at least 500 housing units per square mile. Industrial areas and other zones of distinctly urban land use also were included even if they did not meet the housing density requirement, and the UAs have always allowed gaps of up to 1.5 miles in built-up continuity, under specified conditions. In 1960, the density limit was lowered slightly to 1000 persons per square mile applied to small enumeration areas. Starting in 1970, the UA definitions began to exclude sparsely settled portions of certain incorporated places.

Census Designated Places

The 1950 census also identified and defined many population concentrations outside UAs that were not separately incorporated, including many in New England. These unincorporated places, which were renamed 'census designated places' (CDPs) in 1980, were defined for concentrations as small as 1000; those of at least 2500 were treated as urban. CDPs located within UAs were not separately identified in 1950, but many have been recognized in later censuses.

Together, the recognition of UAs and CDPs added a net 6.7 million to the 1950 urban population, increasing it from 59.6 to 64.0% of the US total (U.S. Census Bureau, 2012: Table 7). Collectively, the 1950 changes altered the US urban definition from one based almost entirely on municipal status and boundaries to one that embraced densely populated unincorporated territory near larger cities, and also recognized qualified population concentrations even if they were not separately incorporated. These modifications, however, still did not include most unincorporated suburban development around smaller cities and towns.

After 1970, some UAs were defined as of that year around certain cities of less than 50 000, and starting in 1980 a UA was recognized for each area whose total population was at least 50 000. Supplementing the official series, Pickard (1967a,b) used the 1970 census criteria to define UAs of at least 50 000 for 1920–40, and also UAs not already defined by the census for 1950 and 1960, mainly because lacking any city as large as 50 000.

By 1990, technical developments permitted replacing manual determination of UA boundaries from detailed maps with interactive analysis of population density at the block level, in turn allowing UA definitions to systematically exclude sparsely settled portions of incorporated places (U.S. Bureau of the Census, 1994: Chapter 12).

Urban Clusters

In 2000, UA delineation was essentially fully automated, and the criteria were loosened slightly to permit inclusion of some development down to a population density of 500 per square mile. But the major development of 2000 was the recognition of urban clusters (UCs), identified by applying the delineation rules for UAs to identify all concentrations of at least 2500 population.

For purposes of defining the urban category, the clusters superseded smaller incorporated places or CDPs, either including them in a cluster, or eliminating them by determining that they did not have as many as 2500 residents at the required density level. Thus, as of 2000, urban territory in principle was defined completely independently of administrative boundaries.

To document the effect of the 2000 changes on the size of the urban category, the 2000 criteria were also applied to 1990 data. The changes would have added a net of 7.0 million to the 1990 urban population and raised the urban share from 75.2 to 78.0% (U.S. Census Bureau, 2012: Table 7).

Changes in the defining procedure for the 2010 census were relatively few, mainly involving qualification of specified types of nonresidential areas as urban if adjacent to a UA or UC.

In 2010, altogether UAs and UCs included 249.3 million people and a land area of 106 386 m^2, amounting to 80.7% of the national total population of 308.7 million, but only 3.0% of the land area. As with most earlier definitions, 'rural' comprised the rest of the national territory.

Useful as the UAs are, they are far less well known than the MAs discussed in the next section. Indeed, the public's chief awareness of UA boundaries may stem from the reduced speed limits that generally apply when entering them (Plane, 2004).

For users who consider 2500 too low a threshold for the urban category, data are available for urban territory by cluster population size. For example, if the threshold for cluster recognition were 25 000 instead of 2500, the 2010 urban share would comprise 73.9% of the total population and 2.6% of the area (U.S. Census Bureau, 2012: Table 6).

United States: MAs

The general term 'metropolitan area' means a large city including its suburbs. The term has developed mostly independently of the related term 'metropolis,' a city of major importance in its country or region; many officially recognized MAs in the United States are not metropolises in that sense. In contrast to a UA, which is a high-density concentration of continuous urban development and thus in a sense a single place, an MA is conceived as a functional entity, embracing both a UA as its core and surrounding territory closely related to that core.

The MAs used in official US statistics since 1950 are 'metropolitan statistical areas' (MSAs) defined by the US Office of Management and Budget (OMB) as a geographic standard for all federal statistical agencies, ensuring that statistics from different agencies will refer to consistent boundaries. OMB defines an MSA as a large population nucleus or core plus adjacent communities having a high degree of economic and social integration with that core. Integration is measured using census data on commuting to work. The Census Bureau conducts the technical work needed to arrive at the individual MSA delineations.

In general, entire counties form the MSA building blocks, so that besides a city and its UA, MSAs typically include more distant satellite communities and much open country. In the 2010 census, MSAs were reported with a total of 258.3 million residents, of which 218.0 million, or 84.4%, were in UAs, while the MSA total land area was 912 992 m^2 of which only 85 177, or 9.3%, was in UAs. UCs within MSAs included another 10.0 million residents and 6520 m^2, leaving 30.3 million residents and 821 295 m^2 defined as both rural and metropolitan (U.S. Census Bureau, 2012: Tables 8 and 9).

Recognizing and Delineating MSAs

The first US official recognition of functional-type MAs came in the 1905 Census of Manufactures, which presented data on 13 'industrial districts' defined in terms of subcounty MCDs. In the 1910 decennial census, 'metropolitan districts' were officially defined, generally in terms of MCDs, which were included chiefly on the basis of a population density of at least 150

per square mile. The list of metropolitan districts was updated and boundaries revised after 1920, 1930, and 1940 (U.S. Bureau of the Census, 1913: pp. 73–77; Thompson, 1948). These were probably the earliest national metropolitan definitions that stated specific criteria (Forstall et al., 2009).

However, definition in terms of subcounty units greatly limited the usefulness of metropolitan districts for the compilation of statistical data other than from the decennial census, since most such data were not available except by county. As a result, in 1949, the US Bureau of the Budget (later renamed the OMB), in consultation with the various statistical agencies, established criteria to define 'standard metropolitan areas' (SMAs) for presentation in the 1950 census.

This called for decisions on four fundamental aspects: (1) the choice of geographic building blocks, (2) the minimum size for qualification as an SMA, (3) how to define the core area of the SMA, and (4) how to determine which if any additional units to include. To maximize their usefulness, generally the SMAs were defined in terms of counties. They included every city of at least 50 000, with the city's county constituting the central core. However, just as with the urban definition, the unusual character of New England county subdivisions resulted in special treatment; the SMAs and cores in those states were defined in terms of cities and towns instead of counties.

Commuting data were chosen for determining whether any counties beyond the core should be included in the SMA. There were no national commuting data at the county level, but transportation and other agencies had conducted many local surveys. The final criteria required 15% of workers commuting to the core for an outlying county to qualify. Counties also had to meet specified requirements of 'metropolitan character,' such as having less than one-third of their labor force engaged in agriculture and at least half their residents living in contiguous MCDs with 150 persons or more per square mile. There were 169 SMAs defined for 1950, consisting of 265 counties and 208 New England cities and towns.

The SMAs were rechristened 'standard metropolitan statistical areas' (SMSAs) in 1959 to emphasize that they were not necessarily suitable as general-purpose MAs, and various other changes were made in the criteria after 1950 (Forstall, 2012).

As the availability of data for them made the SMSAs better known, they could be said to suffer from their own popularity. Some local areas wanted to achieve SMSA status in spite of not qualifying for it under the official rules. For example, in 1959, portions of the New York and Chicago SMSAs were split off to create several separate SMSAs, and the New York and Chicago areas as previously defined were recognized as 'standard consolidated areas' (SCAs), thereby establishing a two-level hierarchy of SMSAs within SCAs. Finally, in 1972, the Nassau-Suffolk SMSA on Long Island was created out of the New York area, although it did not even contain a qualifying central city.

Changes for 1980

The census-defined UAs, first established in 1950, were finally accepted as the basis for defining the SMSA central core, consisting of counties with at least half their population in the UA. To deal with the inconsistencies presented by the Nassau-Suffolk, New Jersey, and Chicago definitions, the criteria expanded the two-level hierarchy of areas. Within SMSAs of 1 million or more, defined strictly according to the published rules, component 'primary metropolitan statistical areas' (PMSAs) were recognized based mainly on specified commuting criteria. Any area in which PMSAs qualified was termed a 'consolidated metropolitan statistical area' (CMSA) while all other areas remained MSAs, thus supplanting the terms SCA and SMSA. Recognition of a PMSA required support from local opinion, which OMB ascertained through congressional offices. The need to recognize both CMSAs and PMSAs emphasized a fifth fundamental question in defining MAs: how to decide when two hitherto separate areas have become a single multicentered area.

After the updating based on the 1980 census, there were 351 areas in June 1983, including 253 MSAs and 22 SCAs comprising 76 PMSAs.

Developments 1990–2010

The 1990 review of the MA standards made only minor changes in the criteria, but many users declared that they should be less complicated, even while recognizing that metropolitan structure had become more complex. During the 1990s, OMB and the Census Bureau undertook an extensive review of the standards, including commissioning proposals by outside scholars (Dahmann and Fitzsimmons, 1995). Revised standards in December 2000 included converting to county-unit definitions of MSAs in New England, although ancillary definitions in terms of cities and towns were retained as 'New England city and town areas.' The commuting level required to include an outlying county was raised from 15 to 25%, and the earlier requirements of metropolitan character (density, recent growth, etc.) were eliminated. PMSAs were replaced by 'metropolitan divisions' but only within MSAs of at least 2.5 million.

The major change for 2000 was the recognition of 'micropolitan areas' around the newly recognized UCs, provided the UC population was at least 10 000. The term 'core based statistical areas' (CBSAs) was adopted for the collective metropolitan and micropolitan areas. Provision was also made for recognizing 'combined statistical areas' (CSAs) consisting of adjacent CBSAs (metro or micro) if their employment interchange was at least 15%, with local support required unless interchange exceeded 25%; the components of CSAs retained their status as CBSAs.

Only a few changes were made in the standards for 2010. The term 'definition' was replaced by 'delineation,' and the delineation of CSAs was revised to qualify inclusion of any adjacent CBSA if employment interchange was at least 15%, without reference to local opinion.

In February 2013, the MSA delineations were updated using estimates of commuting from the 2006–10 five-year American Community Survey (U.S. Office of Management and Budget, 2013). The 2013 updating resulted in 381 MSAs, totaling 262.5 million people or 85.0% of the 2010 US total, compared with 84.9 million and 56.1% in the SMAs in 1950. There were also 536 micropolitan areas, accounting for another 8.8% of the 2010 total and leaving only 6.2% of the population outside CBSAs. Together the CBSAs accounted for 47.4% of the US land area (U.S. Census Bureau, 2013).

The official US MAs have come into wide use by both government agencies and private industries. They also have served as a model for defining MAs abroad (International Urban Research, 1959). Changes in the criteria over time have reflected such factors as the availability of new data and techniques of analysis, more extensive use of the delineations outside of government, and increased interest in urban, suburban, and exurban trends.

Urban Definitions in Other Countries

Definitions Used in 40 Large Countries

The most significant difference in how countries define urban relates to how they delimit the individual urban place. In the first edition of its *Demographic Yearbook*, the United Nations Statistical Office (1948: Table 9) recognized three main types of locality definitions in what is still a useful classification:

(a) Agglomerations without regard to official boundaries or forms of government.
(b) Areas with official boundaries under the jurisdiction of local or "urban" forms of government. These are special areas and do not comprise the whole country.
(c) Relatively small (or smallest) areas or administrative subdivisions with fixed boundaries which, in sum, comprise the whole country. These may or may not be under local forms of government.

The United Nations' (UN's) current biennial projections of world population include 2011 estimates of each country's urban population and a note specifying the country's definition of its urban category (United Nations Population Division, 2012). Forty countries are listed with at least 15 million urban population; together they account for 3057 million or 82% of the estimated world urban total of 3632 million. Based primarily on the information in that publication, the following discussion groups these 40 large countries into nine categories, broadly based on the UN categories of 1948. Following the UN's usage, 'agglomeration' denotes a concentration of continuous urban-type development.

A – Agglomerations, not based on administrative boundaries
A1 – Agglomerations defined primarily by population density: the United States, United Kingdom, Canada, and Australia, with a total urban population of 356 million, use density for small enumeration units to arrive at agglomeration boundaries. Their population thresholds for urban qualification range from 1000 in Canada and Australia to 2500 in the United States and 10 000 in the United Kingdom.
A2 – Agglomerations defined based on urban continuity, which may extend across administrative boundaries: France and Algeria, with a total urban population of 80 million. France's definition requires 2000 residents in the main agglomeration of a commune, defined as consisting of houses and other urban structures separated by less than 200 m. However, it is the whole commune that is treated as urban, as are other communes with built-up continuity with a qualifying commune, even though their population is below the 2000 limit. Thus, France follows an agglomeration approach, but defines the agglomeration in terms of entire communes.
A3 – Agglomerations described as localities, population centers, or places: Mexico, Argentina, Colombia, Vietnam, Venezuela, and Chile, with total urban population of 233 million. Urban thresholds range from 2000 (Argentina) to 4000 (Vietnam). Exactly how localities are defined is not always specified.
A4 – Agglomerations provided they are seats of local administrative units: Brazil and Peru, with a total urban population of 189 million. Available evidence suggests that this criterion includes some very small localities, although their effect on the country's urban total may be trivial.

B – Urban units are municipalities, distinguished from nonmunicipal territory
B1 – Urban units are incorporated municipalities: Japan, the Russian Federation, Nigeria, Pakistan, Iran, Ukraine, Thailand, Poland, Saudi Arabia, and Iraq, with a total urban population of 540 million. Most countries in this group do not cite an urban threshold, but Nigeria uses 20 000 and Saudi Arabia 5000. How closely this urban definition compares with the other categories depends on whether municipalities are tightly or generously defined. For example, Japan's cities, which comprise its urban population, included 90.7% of its population and 57.2% of its area in 2010 (Japan Statistics Bureau, 2012: Table1).
B2 – Most urban units are municipalities, but some are nonmunicipal areas with specified urban characteristics: India, Bangladesh, Malaysia, Morocco, and Myanmar (Burma), with a total urban population of 486 million. India and Bangladesh generally use a threshold of 5000 and Malaysia of 10 000. Myanmar's criteria were not available to the UN in 2012; it is placed here assuming that (like India and Bangladesh) it still follows the model established decades ago by the Census of India.
B3 – Urban units limited to capitals of provinces and districts: Turkey and Egypt, with a total urban population of 89 million. Especially in Egypt (2011 urban proportion 43.5%), this definition probably omits considerable urban-type development.
B4 – Urban units identified largely in terms of cities or municipalities, not necessarily including their entire areas, and sometimes including noncity areas: China, Indonesia, Philippines, Republic of Korea, South Africa, and the Democratic Republic of Congo, with a total urban population of 945 million. The urban criteria for these countries typically are lengthy and detailed and some 'cities' are overbounded. This is especially true of China, whose urban definition is presented in the final section of this article.

C – Urban units are small administrative units (communes). Germany, Italy, and Spain, with a total urban population of 138 million comprise this category. Italy and Spain use a threshold of 10 000.

Changes in Urban Definitions

Some countries have changed therir urban definitions in recent decades. In Western Europe, definitions in many countries used to be based on municipalities, whose territory was largely urban in character. Subsequent amalgamations of local-government units resulted in expanding most municipalities

to include much rural territory (Council of European Municipalities and Regions, 2009: pp. 4–7). This encouraged adoption of urban definitions based on individual agglomerations, for example, in Sweden, Norway, Denmark, and the United Kingdom. Such changes not only improve the preciseness of the urban definition, but also add to the difficulty of making valid comparisons of urban population across countries and over time.

Official Urbanized and Metropolitan Definitions in Other Countries

Besides the countries listed in categories A1 and A2 above, only a few countries publish officially defined urban agglomerations. India's urban agglomerations are defined in terms of contiguous municipalities and nonmunicipal urban outgrowths. Japan has published densely inhabited districts (DIDs) since 1960, based on small enumeration areas, density of at least 4000 persons per km^2 and 5000 total population. Individual DIDs do not cross municipal boundaries, but detailed maps permit identifying continuous agglomerations. Formerly, the DIDs were the basis for defining Japan's urban population.

Many countries define functionally conceived MAs under various labels, generally in terms of minor administrative divisions. Besides the United States, these include Canada, Mexico, Colombia, Brazil, Belgium, Netherlands, Switzerland, Austria, Hungary, the Scandinavian countries, Bangladesh, Japan, Australia, and New Zealand. The defining criteria vary widely and not all countries specify them in detail, but most appear to use commuting data to determine metropolitan boundaries.

Besides these national definitions, some international bodies have presented analogous definitions on their Web sites, such as functional urban areas (European Observation Network, or ESPON) and 'larger urban areas' (Eurostat), supplementing rather than superseding the nationally developed definitions.

The UN's list of largest so-described urban agglomerations (United Nations Population Division, 2012), although widely used, unfortunately is an internally inconsistent mixture of the MA, UA, or city-proper definitions of individual countries (Forstall et al., 2009). Systematic efforts to define MAs or UAs internationally include those by International Urban Research (1959), Hall and Hay (1980), and Moriconi-Ebrard (1993, continued by the Geopolis Web site). Champion and Hugo (2004), Hall and Pain (2006), and Champion (2011) have pointed to evolutionary trends that raise new questions about urban and metropolitan definitions. The unofficial Web sites of Geographia and the Lincoln Institute of Land Policy present extensive data on large world urban areas (Angel, 2012; Angel et al., 2012), and various other Web sites offer population data on cities and towns by country and in some cases on MAs or UAs.

Urban Definitions in China

The People's Republic of China has what may be the world's most complicated and confusing way of defining its urban population. The sources of confusion are multiple and multilayered. The complexity is first compounded by the Chinese household registration (*hukou*) system, which does not consider most migrants to cities as permanent residents and excludes many of them from the city's annual *de jure* population counts. In contrast, the decennial census reports population on a *de facto* basis, producing counts often quite different from the annual count. Moreover, the coexistence of multiple urban and city definitions also complicates the task of defining a city and city population. Finally, rapid development over the past three decades in the country and its major cities, including numerous changes in the urban definition and local administrative boundaries, has also added complexity.

A Chinese city or municipality (*shi*) is an administrative unit, but the 'city' label can be misleading. Large cities refer to those in the categories of prefecture-level and provincial-level cities. There are also many smaller cities (county-level cities) and several thousand towns. The principles used in defining 'urban' within them are similar to those for large cities. Most large Chinese cities today encompass an extensive area, which contains an urbanized core (high-density built-up area), surrounded by numerous scattered towns and large stretches of rural territory, usually with dense farming populations. These 'cities' are so large in area that they are more aptly called 'regions.'

In almost all large cities, the urban core, together with some close-in built-up and rural areas, is divided into 'city districts' (*shiqu*), while the surrounding rural areas (including many towns) are divided into counties (*xian*). The urban administrative area (the collective city districts) generally is larger than what can be called the continuously built-up UA around the core.

Besides referring to the entire region-sized administrative area, the word *shi* is also often used to refer to a smaller area – the aggregate of city districts only. Even more confusing, the term 'city population' (*shi renkou*) can mean the population of any of the following: the city region (including its subordinate counties), the aggregate of city districts, the aggregate urban areas (see below) within the city region, or the aggregate urban areas within the city districts only.

Up until about the mid-1990s, the aggregate of city districts did roughly correspond to the UA for most large cities. However, since then, many largely rural counties have been reclassified administratively as city districts in the pursuit of rapid 'urbanization' (Yew, 2011). In other words, many city districts now include large stretches of rural territory. As a result, in the 2000 census, China's National Bureau of Statistics (NBS) defined two urban categories, city urban and town urban. Under this definition, city urban includes, first, all city districts with a population density of at least 1500 persons per km^2. Second, for other city districts, urban areas are (1) all subdistrict units (*jiedao* (streets), *zhen* (towns), and *xiang* (townships)) that include the city or district government headquarters, or street government offices; (2) subdistrict units with built-up areas contiguous to the units specified in (1); and (3) all other *jiedao* units. Town urban comprises village-level units, which are residents' committees (*jumin weiyuanhui*) or include the town government headquarters, and other units whose built-up area is con-

tiguous to the preceding. Based on that urban definition, China's *de facto* urban population accounted for 36% of the total population in 2000. Many specialists considered the results acceptable and generally comparable to urban counts used in other countries (see, e.g., Chan, 2007).

China's urban definition underwent further changes in 2006 and 2008. The latter definition was used in the 2010 Census and is in use currently. In cities and towns, urban areas consist of residents' committee units where local-government headquarters (city, district, county, or township) are located, and units with built-up structures contiguous to those units. Additional units that are not contiguous but have a population of at least 3000 (such as development zones and mining areas) are also considered urban areas. Based on this definition, the 2010 Census counted 666 million urban population, or 50% of the nation's population.

While the city population statistics from the census and other NBS sources are for the *de facto* population, the *de jure* set published by the public security authorities using local household registers (*hukou*) is widely used within various levels of governments. These *hukou* population data count only the population with legal permanent registration in the area, and do not reflect the actual population in residence. Under China's *hukou* system, each citizen is required to register in one and only one place of (permanent) residence. An individual's *hukou* status defines his or her rights and eligibility for social welfare and various services, including public education and housing, within a specific administrative unit. Since there are often significant disparities in services, especially between rural and urban units, change of one's *hukou* registration is ordinarily not granted even though one has migrated to a new place (Chan, 2010). Some minor changes to the *hukou* system have been implemented locally in recent years and bolder changes are currently being discussed and considered.

For almost all large cities, the *hukou* population is smaller than the *de facto* population because of in-migration of people whose *hukou* remains back in their original place of registration. In some extreme cases, the differences between the registered (*hukou*) population and the actual *de facto* population can be huge. In 2010, in Shenzhen adjacent to Hong Kong, local *hukou* population was only 2.6 million, whereas the *de facto* census population was 10.4 million.

Suburbanization began to emerge around China's large cities in the 1990s and has accelerated in the last decade. Their expanding high-density cores are increasingly encircled by somewhat less dense suburban development. For a variety of analytical and policy purposes, it is very useful to be able to define a metropolitan boundary based on a daily labor-shed concept, as is done in many other countries.

However, there are no official or standard criteria for defining MAs in China. While the MA concept has frequently been mentioned by researchers, often they do not mean by it the daily labor shed. Since commuting data are still not systematically collected or available publicly, some researchers have proposed alternative methods to delimit MAs (e.g., Chan and Forstall, 2012).

Abstract

Planning ranks as a significant social movement of the twentieth century. Its modern history is an ongoing story of achievement, resilience, failure, and adaptation to place, culture, and circumstance. The scope of planning has expanded dramatically from its nineteenth-century origins addressing the challenges of industrial urbanization. Early planning goals crystallized around the themes of health, convenience, and beauty. By mid-century, the guiding ideal was the modernist functional city. After World War II, planning became ensconced in the welfare state. Toward the end of the century, planning came under attack on many fronts, fragmenting its traditional land-use focus into many specialties. In recent decades, the planning agenda has become more diffuse in response to intractable challenges in the urban environment. Sustainability has provided a new focus. In the early twenty-first century, planning operates at many different scales in a variety of forms but land-use allocation, development control, and stewardship of the public realm constitute recurrent themes. The balance sheet of more than a century of modern urban planning in Western cities shows a positive contribution to their productivity, sustainability, and quality of life.

The evolution of urban planning is inextricably linked with the processes of modernization and the nature of modernity. The emergence of planning in Western cities reflected the response of both private interests and the state to problems of accelerated urbanization from the end of the nineteenth century. The agenda and scope of urban planning have subsequently expanded dramatically. Its forms have ebbed and flowed in concert with myriad economic crises, social problems, environmental and demographic pressures, political opportunism, and technological changes. At the start of the twenty-first century, urban planning is a multifaceted set of policy and administrative processes that resist easy categorization.

While an early focus on reforming the physical framework for urban life has braided in various social, economic, and legalistic directions, some common threads have characterized the mainstream history of planning theory and practice. These include a pervasive ideology of holism and the benefit of the 'bird's eye view' in directing urban development; direct involvement in the allocation of land uses; a practical commitment to reconciling the diverse interests of stakeholder groups; an emphasis on order, scientific analysis, and rationality in public policy decision making; belief in the power of environmental improvement to deliver community benefits; and an ongoing faith in the potency of enlightened state intervention to secure the 'public interest' in the face of market failure.

Antecedents and Beginnings

For such a quintessential twentieth-century activity, urban planning has a remarkably long history. But this premodern planning invariably meant rudimentary forms of spatial layout and architectural set-pieces disengaged from broader policy concerns. Indeed, planning was all too frequently co-opted as a mere technical device for the imposition of authoritarian will. Planning as civic design stretches back to antiquity – to ancient Egypt, Greece, and Rome – with the organization of urban spaces manipulated to reflect the dominant political and social order. This thread continues through the grand public squares and piazzas of the renaissance city and into the planning templates for imperial expansion, notably the Vitruvian-inspired Spanish Laws of the Indies of the sixteenth century.

Planned towns were variously seats of government, ostentatious displays of autocratic power, military footholds, and service centers for land settlement schemes. Rectilinear, gridiron, or chessboard street plans were the most time-honored morphologies, but by the start of the nineteenth century these models were being studded with open spaces and framed by belts of parkland. Since antiquity, ideal cities assumed a variety of alternative geometries. Radial plans would decisively influence the first generation of early modern planners. Dating from the beginning of the eighteenth century, Karlsruhe (1715) in Germany became one exemplar for a new form of street pattern that was both aesthetic and functional in fanning out from a central edifice.

A more modern urban planning began to emerge in the late nineteenth century to address challenges unleashed by industrial urbanization. Existing narrowly focused administrative procedures and primitive building regulations were ill-equipped to address an interdependent set of new challenges: unprecedented rates of urban population growth; housing shortages and overcrowding; new forms of economic enterprise and infrastructure needs; and a rising tide of environmental pollution.

Diverse modes of thought and practical innovations were tapped to help shape the new discourse of planning. At the theoretical end of the spectrum, for example, a nexus was forged between a longer tradition of social and economic utopian thought and the newer notion of better cities through works like James Silk Buckingham's *National Evils and Practical Remedies* (1849) and Edward Bellamy's *Looking Backward* (1887). Other thinkers, like the influential anarchist Peter Kropotkin, looked toward a more decentralized society aligning village life with new modes of production. The most substantial experiments in industrial decentralization were more socially conservative. These were the planned industrial villages expressing an emergent form of welfare capitalism geared to educating and disciplining a productive labor force. What Walter Creese in *The Search for Environment* (1966) called

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74015-3

the Bradford–Halifax School of model village builders in the English Midlands developed into full-blown community building in places like Bournville and Port Sunlight. The same sort of settlements arose in continental Europe and the United States, for example, George Pullman's eponymous industrial community near Chicago.

Utilitarian issues preoccupied reformers within the cities proper, as basic infrastructure (transport, water supply, sewerage) struggled under new conditions of rapid growth. Poor housing conditions for the growing working class in the form of high-density slum and tenement dwellings became a major concern. Exposes by reformers like New York's Jacob Riis in *How the Other Half Lives* (1890) shocked middle-class sensibilities. Philanthropic model lodging houses and stricter regulations over space standards for rooms, dwellings, allotments, and, in turn, streets ensued. Provision of parks and open spaces was another major concern. Utilizing the organic metaphors that were so prevalent in early planning propaganda, parks were the 'lungs of the city' and needed to be reserved in advance of development. Citizens improvement associations, the precursor to civic art and 'tidy towns' movements, provided a bottom-up chorus of complaint. A major theme through all of this was the need to secure higher standards of public health and hygiene, a crusade that extended to cognate missions of social, moral, and cultural cleansing. Those who could afford to fled the city for the suburbs. Elite low-density communities such as Riverside (1869) near Chicago helped advance planning technique.

Synthesizing ideas in the air, the early basic precepts of planning were expressed through a rich palette of modernist thought. An American contribution was the park system – the concept of interlinked networks of open spaces mixing formal and informal elements and parkways developed by Frederick Law Olmsted Sr., that gave cities like Boston, Denver, and Kansas City a green legacy enjoyed by later generations. The enormously influential garden city idea was similarly associated with an individual, British shorthand reporter Ebenezer Howard, and advanced in his book *To-morrow: A Peaceful Path to Real Reform* (1898), reprinted as *Garden Cities of Tomorrow* (1902). At its most visionary, the manifesto called for clusters of new, self-contained 'slumless, smokeless cities' of limited size on community-owned land as an alternative to the sprawling urban-industrial city. Alternative new urban structures were mooted. In 1892 Spanish engineer Arturo Soria y Maya invented the idea of the linear city (*la ciudad lineal*), which resurfaced in twentieth-century forms such as Edgar Chambless's Roadtown (1910), the ideas of the Soviet de-urbanists in the 1930s, and corridor city planning in the 1960s.

A string of seminal contributions signposting ways ahead emerged in Europe in the late nineteenth century. Town extension planning and land-use zoning were already accepted municipal practices in Germany before 1900. Important texts were Reinhard Baumeister's *Stadterweiterungen in technischer, baupolizeilicher und wirtschaftlicher Beziehung* (Town Expansions Considered with Respect to Technology Building Code and Economy, 1876) and Joseph Stubben's *Der Städtebau* (1890). The *Lex Adickes* regulations for Frankfurt in 1891 prefigured land-use zonation based on sets of standardized regulations. Baron Haussmann's extraordinary transformation of Paris under the patronage of Napoleon III from a largely medieval city into a modern masterpiece of boulevards, star-points, and strategically located public buildings had begun in the 1870s. The ambitious 1859 extension plan of Ildefons Cerdà in Barcelona was an even earlier initiative. A very different aesthetic to these large-scale interventions was that of Viennese architect Camillo Sitte whose *Der Städtebau* (1889) helped codify more artistic, intimate, and historically sensitive techniques for the modern 'art of designing cities and suburbs.'

International exhibitions provided unique opportunities to showcase new urban planning ideas as planned cities in microcosm. The most sensational synthesis was the 1893 World's Columbian Exposition in Chicago. This collaborative integration of grand architecture, landscape design, public art, and early amusement park was overseen by local architect Daniel Burnham, who was to emerge as the leading American architect-planner of the early 1900s.

The crucial intellectual breakthroughs made simultaneously around the Western world in the 1880s and 1890s were recognition of the limitations of piecemeal improvement, the interconnectedness of urban life, and the necessity for more coordinated intervention to avoid the undermining of the social order through outbreaks of disease, community dissent, and loss of economic competitiveness. A new approach was being invented around the world adapted to particular institutional circumstances: town planning in Great Britain, city planning in North America, *städtebau* in Germany, *planificación urbana* in Spain, and *urbanisme* in France.

The First Half of the Twentieth Century

At the turn of the last century, modern planning goals crystallized around recurrent themes of convenience, efficiency, healthfulness, beauty, and order. The actual means to these ends were quite diverse, ranging from totally planned landscapes through selective interventions in the urban fabric to new regulatory frameworks for private development. Certain kinds of planning assumed a cultural distinctiveness. House-and-garden were at the center of British concerns, France was known for its monumentalism, while planning advocates looked to Germany for its innovative land management and to the United States for the business-minded aestheticism of city beautiful thought. The planning movement had become genuinely international. Even a relatively closed Asian country like Japan, in acknowledging the importance of modernization in economic and political advancement, had discovered Western planning ideas through study tours and private visits. Political alliances were crucial for the export of knowledge, so the British impact was strongest in Commonwealth nations and French ideas in various francophone settings.

Major conferences were important agents in the diffusion of knowledge. A spin-off from Howard's Garden City Association (1899; renamed the Town and Country Planning Association in the early 1940s) was the International Garden Cities Association (1913), which would evolve into the International Federation for Housing and Town Planning. Information sharing would be damaged by World War I, but planning was well established as a global movement with astonishing commonalities of purpose and method in diverse settings. With that came moves to institutionalize and inevitably

bureaucratize the activity as a genuine profession occupying the interstices between the traditional built environment disciplines of architecture, surveying, and engineering. Urban planning was also developing its own methodology, with the accent on scientific civic surveys, an extension of settlement worker investigations. Scottish polymath Patrick Geddes supplied the requisite mantra of 'survey-analysis-plan.'

In the English-speaking world, several interconnected events in Britain in 1909 would have major reverberations, especially around the anglophone world: the first formal town planning course started with establishment of the William Lever-endowed Department of Civic Design at the University of Liverpool; Raymond Unwin's classic *Town Planning in Practice* appeared; and the first planning legislation was passed in the form of the *Town Planning, Housing etc* Act. The British Parliament was told of the government's intention to realize 'the home healthy, the house beautiful, the town pleasant, the city dignified, and the suburb salubrious.' The following year, the Royal Institute of British Architects organized an international conference and exhibition that attracted the leading names in world planning and showcased the state of the art.

Early incursions into planning controls were cautious, with governments mindful of private property rights. The British law was initially restricted to zoning for new extensions only but was later extended to existing development. Land-use zoning established itself as the standard form of microregulation in the United States and elsewhere. A popular early mode of zoning was the residential district, a concept that was grafted readily onto existing local government regulations and widely invoked as a tool of social exclusion. A 1916 New York City zoning ordinance introduced novel controls on building height and shape that led to the Manhattan 'wedding cake' skyscraper form. It was not until the historic 1926 US Supreme Court case *Euclid, Ohio vs. Ambler Realty Co*. that the legal validity of planning was finally confirmed in America. British and continental models interconnected planning and zoning, but in the United States city planning commissions and zoning boards could pursue independent agendas.

The early twentieth century is distinguished by some landmark plans that codified modernist planning ideas. The 1901 plan for Washington, D.C., by the Senate Park Commission headed by Daniel Burnham reconfigured Pierre L'Enfant's eighteenth-century plan into a monumental triumph for city beautiful ideas. Many plans for American cities would follow, but the most impressive was the privately sponsored *Plan of Chicago* (1909) by Burnham and Edward Bennett. Artistic in presentation and regional in scope, it set a new standard for comprehensive planning. Edward Lutyens's New Delhi (1912) transplanted grand manner planning to an imperial context. The 1911–12 international competition for the new federal capital of Australia produced a unique survey of early modern planning thought. The winning scheme by Walter Burley and Marion Mahony Griffin, both former associates of Frank Lloyd Wright, was a brilliant landscape synthesis of garden city, city beautiful, and deeper democratic ideals. The most idealistic plan of its day was the footloose *World City for Peace* (1912) by American sculptor Hendrik Anderson and French architect Ernest Hébrard. The multivolume Regional Plan of New York masterminded by Thomas Adams in the late 1920s was the archetypal pragmatic, professional, growth-oriented plan of the interwar period. A celebrated critique by urbanist Lewis Mumford channeling the decentralist ideas of the rival Regional Planning Association of America branded the scheme as dinosauric in entrenching rather than curbing trends toward megalopolitan development. Mumford had further clashes with Robert Moses, a powerful New York official known as the 'master builder' with a penchant for large-scale and often ruthless public works.

Mumford was deeply influenced by the garden city movement and advocated a more organic, environmentally sensitive variant of regional planning. While stopping short of Howard's dream of a 'better, brighter civilization,' garden city advocates campaigned tirelessly for new towns. Their successes were modest but resulted in impressive showpieces of planning in practice. Two British garden cities were built: Letchworth (1904) designed by Raymond Unwin and Barry Parker and Welwyn Garden City (1919) by Louis de Soissons. Welwyn was conceived as an overspill satellite community for London, an idea readily taken up elsewhere. An early German response was the fringe *grossiedlung* with apartment blocks of social housing. In the United States, echoes of the garden city notion can be read into the 1920s speculative sunbelt 'new towns' such as those designed by John Nolen in Florida; the New Deal towns of the late 1930s such as Greenbelt, Maryland sponsored by Rexford Tugwell's Resettlement Administration; and Clarence Stein and Henry Wright's Radburn, New Jersey, with its cul-de-sacs and 'superblocks' representing an experimental 'garden city for the motor age.'

The garden city label and concept was translated to many countries: cite-jardin, gartenstadt, ciudad jardin. The most ubiquitous application was to suburban rather than new town settings, becoming more popular and prolific through the prosperous 1920s in concert with rapid suburbanization generally and with privately master-planned communities often leading the way. These ventures refined further an enduring amalgam of site planning ideas revolving around house-and-garden living, hierarchical street systems, provision of open space and public facilities, and attention to landscaping and streetscape qualities. Clarence Perry synthesized these ideas into the widely influential notion of cellular 'neighbourhood units' but the low-density suburban ideal reached its zenith in Frank Lloyd Wright's *Broadacre City* dream of the early 1930s.

Other expressions of modernism were more vertiginous. New York City's Rockefeller Center in the 1930s foreshadowed the penchant for large-scale urban redevelopment. The most startling theoretical schemes were those of European theorists like Auguste Perret, Ludwig Hilbersheimer, and most famously the messianic Swiss architect Le Corbusier. Through the 1920s, Le Corbusier worked his way through a succession of urban utopias – La Ville Contemporaine, City of Three Million Inhabitants, and the La Ville Radieuse – to perfect a design vocabulary of towers-in-parkland, multilevel transportation systems, and functional land-use segregation. His *Plan Voisin* applied these ideas to a portion of central Paris, sweeping away narrow streets and 'diseased quarters' for a forest of cruciform high-rise tower blocks. The legacy of these ideas can be seen in large-scale state housing programs and planned capital cities such as Chandigarh and Brasilia. The guiding spirit here was architectural modernism, and emerging out of the

deliberations of CIAM (*Congrès internationaux d'architecture moderne*) was the Athens Charter – the definitive town planning manifesto of the 1930s for 'the functional city' distinguished by specialized transportation and freeway systems, high-rise buildings, extensive open spaces, and planned dormitory communities.

Postwar Master Planning

World War II delayed implementation of this blueprint but unleashed a universally strong planning impulse under the banner of postwar reconstruction. In many European cities, the necessary reconstruction was as much physical as ideological. But in most Western nations cross-political agreement on the relevance of state involvement in urban development processes moved planning decisively beyond the rhetoric, experimentation, and broad theoretical acceptance attained by the 1930s into the realm of implementation. Through the 1950s, the scale of planning activity grew significantly as planning settled comfortably into the policy machinery of the welfare state. The bureaucratization of planning was underpinned by a steady professionalization and growth in tertiary education to train the larger numbers of experts required.

The dominant discourse was that of urban planning as an unambiguously beneficent activity of government: comprehensive, technocratic, scientific, and socially progressive. More was better if cities were to remain healthy, efficient, prosperous, and beautiful. The major focus was on land-use planning. The elements of modernist planning had surfaced before the war and were now synthesized into a total ensemble embracing master plans; comprehensive redevelopment of the inner city; monofunctional land-use zoning; high-rise social housing towers; low-density middle-class suburbs; planning and replanning of residential areas as neighborhood units; freeways, ring roads, and pedestrianized town centers; green webs of open space; industrial decentralization; and new towns. From mid-century, these planning ideas, variously interpreted and combined, but broadly accepted by architects, developers, and government, made decisive impacts on urban landscapes worldwide.

All-encompassing metropolitan blueprints assumed a central status. Three early master plans from the mid-1940s influencing many that followed were those for London, Stockholm, and Copenhagen. Patrick Abercrombie's definitive plans for the city and county of London, 1943–44, were built around a cellular community structure, an encircling greenbelt to contain suburban sprawl, and a ring of new towns. Sven Markelius's general plan for Stockholm 1945–46 skillfully integrated transportation, land use, and environmental planning, with new subcenters developed around railway stations. And the first Copenhagen finger plan of 1947 also anticipated the transportation corridor and green wedge planning that would gain popularity from the 1960s when encircling greenbelts seemed doomed by escalating suburbanization.

Postwar city strategies targeted both obsolete inner areas and planning opportunities on new greenfields sites. Urban renewal schemes involving high-rise housing, upgraded transportation infrastructure, private- and public-sector offices, and other new uses sought to modernize the late industrial city, frequently doing so at the expense of existing community structure and historic building fabric. Efficient urban mobility remained a major concern, and an influential prospectus was Colin Buchanan's *Traffic in Towns* (1963), which legitimized planning ideas to become commonplace in Britain and internationally such as clearways, flyovers, pedestrianized precincts, and multistorey car parks. The garden city dream was kept alive in new towns. The most heroic program was in Britain, with the *New Towns Act* 1946 facilitating construction of over 30 new towns by public corporations between 1947 (Stevenage) and 1970 (Milton Keynes). Similarly, around Paris a ring of *villes nouvelles* was conceived within an ambitious 1965 master plan (SDAURP). Private-sector new towns (such as Reston and Columbia on the east coast) were more common in the United States. Everywhere, however, and even if it did not look like it, considerable planning energy was devoted to the processes of facilitating suburban development. The high point of technocratic master planning allied to 'scientific' methodologies and modernist architectural solutions was the late 1960s.

Postconsensus Urban Planning

The new world order that emerged in the 1970s constituted a markedly different context. The notion of the centralized, benevolent state crumbled. Economic policy was forced to look beyond the industrial fordism that had been the touchstone of social progress in the first half of the twentieth century. Dissent over unpopular wars and civil rights spilled onto the streets. More frequent calls were heard for greater community participation and self-help. The sterility of modern design trends was challenged. And the environmental movement awakened. In the face of these challenges, even if planning seemed to be realizing prewar dreams in physical terms, it was not always delivering attractive, equitable, and environmentally sound outcomes.

As the world changed, urban planning came under attack on many fronts: for standardized formulaic solutions, freeway proposals slicing through established neighborhoods, destruction of historic buildings, minimal attention to social issues, and facilitation of suburban sprawl. A famous critique of mainstream planning ideology with its fixation on the steamroller 'radiant garden city beautiful' was Jane Jacobs's *The Death and Life of Great American Cities* (1961). Robert Goodman portrayed planners as the 'soft cops' in *After The Planners* (1972). If the demolition of the award-winning planned housing project Pruitt–Igoe (1972) in St. Louis was symbolic of the end of architectural modernism, it also represented the loss of faith in the 'brave new world' international-style planned landscapes of the postwar era. Other countries had their version of Pruitt–Igoe, such as the partial collapse of the high-rise Ronan Point development in London in 1968. Many unpopular grand redevelopment plans for Western cities were scuttled by citizen action during these years. But there was also a higher-level backlash against planning evident in the 1980s that fundamentally questioned the central role of government planning as an agent for the wider public interest. The political consensus that had been the platform for the rise of urban planning after World War II was severely strained.

New directions consistent with a search for postmodern solutions were sought as negative impacts from the decline of traditional industries took hold. There were moves to reinvent central cities hit hard by suburbanization and industrial abandonment. The American developer James Rouse promoted the festival marketplace concept to rejuvenate the retail appeal of struggling downtowns like Boston and Baltimore. Observers like William Whyte in his *The Social Life of Small Urban Spaces* (1980) began to turn their attention to the design and use of the public realm in more human-centered ways. Alternatives to both wasteful low-density and bleak high-rise housing were more explored. A more environmental approach to design also developed, a particular concern for more liveable and safer spaces captured by C. Ray Jeffery's *Crime Prevention through Environmental Design* (1971). Planning responded to its own crises of legitimacy by fragmenting into more popular smaller targets such as advocacy planning, participatory planning, cultural planning, economic development planning, transportation planning, historic preservation, and urban design. In recent decades, the planning agenda has become more diffuse as cities have become ever more difficult to manage.

New Millennium Planning

In the early twenty-first century, cities face a raft of pressures; some enduring if updated from the early days of the town planning movement, others new and just as troublesome. Financing constraints, calls for greater participation and accountability, transport congestion, environmental degradation, continuing sprawl, social polarization, peak oil, global warming, and risks from extreme events and disasters are some of the problems now being confronted. Balancing productivity and livability is an ongoing challenge. Not all places have to contend with growth issues; a 'shrinking cities' syndrome is also evident with long-term structural economic decline. Globalization has introduced intense competitive pressures. The rise of global cities, captured in Saskia Sassen's *The Global City* (1991), is associated with new growth vectors: the information and service economies in particular. New York, London, and Tokyo are the three alpha cities dividing up a 24-h world. Below them is a fiercely competitive battle for prominence in particular time zones across the eastern and western hemispheres. Michael Porter's *The Competitive Advantage of Nations* (1990) was influential in shaping public policy agendas and planning responses.

Unlike an earlier era when the state would assume fiscal leadership, the new era of neoliberalism instead sees governments of all political persuasions privileging market forces. Reaganism and Thatcherism in the 1980s were the templates, although the Global Financial Crisis of 2007–10 and its lingering effects prompted a rethink and a return in some sectors to more command and control interventionism. Nevertheless, the early twenty-first-century city is one where ideologies of privatization, commercialization, and entrepreneurialism hold sway. The manifestations within planning systems have been diverse and include reforms to cut the red tape of planning regulation, the preference for public–private partnerships to share risks and responsibilities in a climate of declining public funding, elevating city branding strategies to public policy, and designating hot spots for accelerated development with special administrative relationships outside everyday arrangements. The enterprise zone concept is a related outcome of the latter trend, intended to stimulate free enterprise through financial incentives with a minimum of bureaucratic rules. Energetic city-states like Hong Kong and Singapore served as a model.

Urban regeneration has become a key policy concern. Three sets of circumstances are common: offering opportunities to redevelop often vast tracts of redundant industrial and port lands; ensuring the vitality of central areas in decline because of loss of commercial activity to rival suburban centers as captured in Joel Garreau's *Edge City* (1991); and reinvigorating the decline of former suburban showpieces like shopping malls and planned social housing estates. In the shift from greenfields to brownfields (industrial) and grayfields (underdeveloped suburban lands), a common approach is precinct development based on purpose-created agencies created to fast-track development with major private-sector involvement. Recurring land-use types include office towers and business parks, higher density private housing, waterfront upgrades, adaptive reuse of historic districts, convention centers, sporting stadia, trade centers, and casinos.

The London Docklands redevelopment centered on Canary Wharf, which began in the 1970s, first showcased showpiece regeneration possibilities on an expansive scale. Exemplars worldwide have followed, including Battery Park City in Manhattan, the Tokyo Waterfront, Barcelona, Marseilles, Bilbao, Liverpool, and Vancouver. Progressive civic leadership is a recurring feature of many successful transformations. In Germany, International Building Exhibitions from the early 1980s featured actual physical demonstration projects. Emscher Park (from 1999) in the former powerhouse of the Ruhr comprises over 90 separate employment and cultural projects, many drawing on the region's industrial heritage. Major urban regeneration strategies employ eye-catching iconic projects. The Grands Projets of former French presidents Mitterrand and Sarkozy in Paris reflect the highest-level political priority to quality design outcomes. The staging of hallmark events like the Olympic Games is now linked to transformative postgame urban strategies. The London Games (2012) were described as the 'regeneration games' for improving the quality of life in the inner eastern suburbs of the Lea Valley. Megaprojects such as large infrastructure and city gateway schemes in various cities are all geared ultimately to increasing accessibility and connectivity and enhancing competitiveness in what Manuel Castells in *The Rise of the Network Society* (1996) evocatively called 'the space of flows,' but all carry inherent financial and political risks.

The integration of land use, transport planning, and design has become a new priority. Peter Newman and Jeff Kenworthy's *Cities and Automobile Dependence* (1989) was an influential sourcebook that documented the costs of car reliance in low-density cities, but the real breakthroughs have been in practical schemes. European-style light rail systems have proven popular worldwide. They were adopted progressively in many American cities from the 1980s, even in notoriously car-dependent cities like Los Angeles (1990) and Houston (2004). Promoting active transport usage has become an integral aspect of urban public policy. For example, citywide bicycle rental programs, which

began appearing in the 1970s and received a fillip from the Parisian (Velib) scheme launched in 2007, numbered over 400 worldwide by 2012. Superior urban design standards are now factored into expansion and retrofit projects. The Danish urbanist Jan Gehl, author of *Cities for People* (2010), has been an influential promoter of walkability, cyclability, and liveliness in human-scaled central cities.

Culture has assumed a growing importance in urban revitalization, its possibilities sketched in influential tracts such as Charles Landry's *The Creative City* (2000) and Richard Florida's *The Rise of the Creative Class* (2002) where place-based creativity and mobile artistic professionals are seen as fundamental drivers of economic growth. Many cities have opted for cultural planning strategies. The most successful transnational program is the annual European City of Culture launched in 1985 and targeted at city marketing, physical regeneration, and tourism. Culture has been employed at various levels in urban development processes, including major investment in new flagship performance spaces, museums, and art galleries; development of cultural precincts and 'quarters'; support for public art and more grass-roots ventures; and the staging of seasonal activities such as fairs, music festivals, and cinema in the park.

The dominant planning paradigm in organizing responses to the major challenges presented by the twenty-first century city is sustainability. The standard definition of sustainable development is 'development which meets the needs of the present without compromising the ability of future generations to meet their own needs.' This concept was popularized in *Our Common Future*, a report published by the United Nations' World Commission on Environment and Development in 1987, also known as the Brundtland Report. It is generally accepted that sustainable development calls for a convergence between economic development, social equity, and environmental protection.

Endorsed and elaborated at the highest level of the United Nations beginning with a landmark Summit in Rio de Janeiro in 1992, these ideas have inexorably devolved to guide state, provincial, regional, and local planning strategies worldwide.

Sustainability has helped to reinvigorate the mission of planning and has proven adaptable to different interpretations, although concrete policy implementation has proven difficult. It guides many different types of strategic initiatives and regulatory control, but environmental goals involving protection, conservation and replication of natural systems tend to be paramount. Progress has been made on indicators or metrics to measure the impact of sustainable development policies. Green building rating systems for water and energy efficiency, materials recycling, indoor environmental quality and other criteria have been institutionalized in many jurisdictions, for example, LEED (USA), CASBEE (Japan), NABERS (Australia), and BREEAM (United Kingdom). Sustainability aims are now routinely incorporated into environmental assessments of new development. Sustainability has also reinvigorated attention to the important links between human health and the built environment. This was an early theme of the planning movement nurtured through the postwar period and by later contributions such as Leonard Duhl's *The Urban Condition* (1963) and then the World Health Organization's Healthy Cities Program (1987), but only since the 1990s has there been a renewed interest in urban form. Another emerging issue has been planning to secure sustainable food supplies; Carolyn Steel's *Hungry City* (2008) highlights the need for urban food planning.

New approaches to urban and suburban development channel broader imperatives toward sustainable design. These share similar objectives for a sustainable urbanism but with different emphases. What American planners call Smart Growth strategies encompass anti-sprawl measures, higher development densities, preservation of rural land and greenspace, and designation of urban growth boundaries. Portland, Oregon is considered an exemplar of such policies. Transit Oriented Development (TOD) promotes the creation of compact communities centered around high-quality public transit systems to lessen dependence on cars. One of the earliest and most successful examples of TOD is Curitiba in Brazil, based on an extensive bus system network. The New Urbanism is associated with American architect-planners like Andrés Duany, Elizabeth Plater-Zyberk, and Peter Calthorpe. It emphasizes walkable communities featuring mixed-use development with a range of housing types and commitment to superior design qualities enforced by architectural-based codes. The seasonal vacation community Seaside (1984) on the Florida Panhandle coast embodies the connection to neo-traditional design inspired by vernacular styles. Poundbury (1993), designed by Luxembourg designer Leon Krier, captures a British version drawing on English vernacular design traditions. The impact of the New Urbanism can be traced into master-planned communities, gated communities, infill projects, and 'grayfield' redevelopments.

Climate change has assumed a prominent place in sustainable development thinking. It was cemented in the public imagination by the documentary film *An Inconvenient Truth* (2006) narrated by former U.S. Vice President Al Gore. Setting the global agenda is the United Nations Intergovernmental Panel on Climate Change established in 1988 to provide comprehensive scientific assessments of changing climatic parameters, risks, consequences, and responses to the world's continuing dependence on carbon-based energy. Major assessment reports are released every few years. The role of spatial planning in developing both mitigation measures to reduce emissions and adaptation measures to ameliorate the effects of climate change has grown. The mitigation measures encompass actions around reducing car travel, increasing energy efficiency, and encouraging alternative energy sources; the adaptation measures pertain more to controlling development in high-risk areas.

Cities are now expanding and even merging to create urban settlements on an unprecedented scale. Mega city-regions and corridors are emerging in various parts of the world to become the new engines of both global and regional economies. Central government now has much greater awareness of the role of cities in economic development. There has also been a resurgence of metro-regional strategies and strategic visions to address the management of powerful centrifugal forces for dispersion, coordinate provision of infrastructure, facilitate joint ecological projects, secure balanced economic development, and guarantee spatial equity in terms of access to opportunities. Planning systems are struggling to keep up with the challenges and pressures. Moves toward addressing problems of political fragmentation through constituting new

unitary city-regional authorities are evident but struggle because of entrenched political opposition to radical reform. Incremental steps can be taken through voluntary regional agreements evincing the moves toward the popular theory of collaborative planning. International treaties can encourage the positive convergence of city responses to key issues, such as climate change. This has been evident in 'borderless' Europe. The European Spatial Development Perspective enacted in 1999 constitutes a policy framework aimed at balanced and sustainable spatial development. A Territorial Agenda agreed to by EU members in 2007 builds on the earlier compact. There is a strong theme of orderly management of polycentric city-regions. Randstad Holland was an early model, popularized by Peter Hall in *The World Cities* (1966).

The Achievements and Legacy of Urban Planning

Urban planning ranks as a significant social movement that came of age in the twentieth century. Its modern history is a complex and ongoing story of achievement, failure, resilience, and redemption. Over time, chameleon-like, it has taken a role that has been constantly adapted to place, culture, and circumstance. It is a history of both continuities (the quests for health, justice, efficiency, environment, and amenity) and discontinuities (in response to global technological, economic, political, and climate shifts).

Modern urban planning is now over a century old. The scholarly study of urban planning history burgeoned in the last quarter of the twentieth century, with an International Planning History Society formed in England in 1974. Planning over the decades since then has grown further in complexity at different scales, driven by a mix of motivations, and often striving to reconcile top-down and bottom-up aspirations. It has numerous public and private stakeholders enjoying different levels of power and influence. It is defined in different ways as community building, urban management, development control, and strategic planning. And it is rare, at least at the supra-local level, to find a singular planning department as a self-contained or even peak coordinating agency. Instead, planning is usually distributed across many agencies dealing with transport, economic development, communities, and environmental protection. Modern urban planning in Western countries is far from monolithic and even at the most general level assumes different cultural inflections – for example, British town and country planning focused on managing land use, European urbanism on design, and American planning with its social and economic policy orientation. The core foci remain regulation of development, design of the built environment, and valuation of the public realm.

Historically, planning thought has experienced its greatest periods of innovation in response to periodic social crises – explosive population growth, war, global economic shifts. Planning's aspirations have always soared above the practicality of their comprehensive realization, being buffeted and reshaped continually by broader social constraints. At times, planning has been a deeply flawed practice, with outcomes often the reverse of those intended (destruction rather than enhancement of community, promotion of segregation rather than social cohesion, dreary townscapes rather than inspired urban design). This is planning's 'noir' side. Always more political than merely technical, sometimes it has been exploited as a tool of social control to pursue policies of exclusion, segregation, and marginalization.

At the same time, there is a raft of value-adding achievements in areas such as open space provision, affordable housing, mass transit, public infrastructure, development of liveable, new communities, injection of sanity into myriad land-use determinations, and protection of natural and cultural resources. There is general community acceptance that constraints on individual freedoms and property rights may be warranted for collective benefits. On balance, urban planning initiatives have meant that a significant proportion of humanity on every continent finds itself living in better circumstances at the beginning of the twenty-first century than 100 years previously. World Town Planning Day, an initiative launched in the late 1940s, is now celebrated worldwide every November.

Abstract

This article summarizes the historical and contemporary urban planning practices and policies in China, and discusses China's rapid urbanization following its economic reform since the 1980s and the role of urban planning in promoting urbanization and stimulating economic growth.

Urban planning could be understood as the professional work of guiding urban development through making physical plans and development regulations, or more broadly as social, economic, environmental, and constructive efforts to make an urban area a better, healthier, and more just place to live, work, and get around. If urban planning means physical development, then China is one of the civilizations with a long history and rich experiences of urban planning activities. Planned towns were built before the Zhou Dynasty of 1000 BC when town planning principles and rules were officially recorded in *Zhou-Li*: *Kao-gong-ji* (Figure 1). If urban planning includes physical as well as economic and social development, then the urban planning practice in China has shown an approach and a consequence different from that in Western countries.

Both traditional Chinese culture and preferences of China's rulers over 4000 years have impacts on China's urban planning practice. The former determines the location, space order, and form of towns and buildings based on social norms and cultural beliefs, such as *Feng-Shui*, and it has more consistent influence; the latter defines and regulates planning activities following the ideology of the government at that time and personal biases of the ruler in power.

Figure 1 The ideal city model defined in *Zhou-Li*: *Kao-gong-ji*, the Zhou Dynasty, 1000 BC. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

Urban planning activities in China may be divided into three periods:

1. Recorded urban planning activities and planned cities in ancient and medieval China from the Shang Dynasty, 1700 BC, to Middle Qing Dynasty of 1840 (the year of the Opium War, which ended with the China–Britain Treaty of 1842, the symbol of China's entering into the quasicolonial age of modern times in Chinese history);
2. Urban planning in China's modern times from Middle Qing Dynasty to the Republic of China in mainland in 1949 with planning activities in China's early industrial and colonial cities;
3. Contemporary urban planning in the People's Republic of China after 1949 to present. This is the period with a fluid trajectory of urban policy and planning practice. The present urban planning practice accompanies large-scale urbanization and rapid growth of urban economy and urbanized areas. It is in this period that the function of urban planning shifted significantly from a central government's tool to implement central decisions under the planned economy to a local strategy to stimulate economic growth in the post-reform era.

Taiwan, where the government of the Republic of China has operated since 1949, and Hong Kong and Macau, China's two Special Administration Districts that used to be ruled by foreign administrations, follow regulations and principles different from the planning practices on the mainland. However, with the adoption of the open-to-outside reform policies since 1978, the differences between urban planning practices in the mainland and in Taiwan, Hong Kong, and Macau have become much smaller. While cities in various ethnic Chinese societies still show some influences of traditional Chinese culture, their appearances are becoming more similar in the age of globalization. Neoliberalism policy and 'selling the place at the global market' promotion are popular in all Chinese cities whether they are located on the mainland or across the Taiwan Strait.

Urban Planning Activity in Ancient and Medieval China (from Shang Dynasty, 1700 BC, to Middle Qing Dynasty, 1840)

Ancient Human Settlement in China and Feng-Shui

The oldest human settlement of about 10 000 years ago in China is recorded in *I Ching* or *Yi Jing*, one of the oldest Chinese classic texts in 1000 BC. Archaeologists found remains and sites

of ancient human settlements in several areas in China, including Lon-shan village and Ban-po village; most of these settlements were built 5000–7000 years ago. The plan and form of these settlements do not show recognizable planned patterns, but they do seem to follow some sort of order based on certain cultural and/or religious beliefs, as found in many ancient settlements of other ancient civilizations (A. Rapoport has done excellent work on the topic.) The cultural beliefs and social norms were developed gradually, and they eventually became important guidelines in planning and building towns and houses in the ancient Chinese society. The most famous guidelines are Feng-Shui (meaning the Wind and the Water).

Feng-Shui is a summary of experience learned in building houses, making tombs, and planning towns, plus many cultural beliefs passed on for generations among Chinese people. Feng-Shui lists a group of regulations for location selection and orientation. According to Feng-Shui, a town should be located in an area backed by mountains at the north, facing a river/lake at the south, with roads and agricultural fields on the east and west (Figure 2). Given China's geographic location in the northern hemisphere, the ideal location and orientation seem based on practical considerations – orienting to the south for direct sunlight and to block wind from the north. Other Feng-Shui regulations also provide advices for locating a house and making a layout of a room.

Figure 2 *Feng-shui* principles for selecting an ideal location of a town. Reproduced from Peng, G., 2001. History of Chinese Architecture. China Architecture and Building Press.

Recorded Planned Cities in Ancient and Medieval China

Guided by scholars' research findings, archaeologists have found sites and remains of several important ancient cities. There are two types of ancient cities: formal cities as capitals of states, kingdoms, and the nation and informal ones as main trading and transportation hubs. Both show certain planned patterns.

Chang-an city, the capital of the Tang Empire (618–907, Xi'an today), located in the Shan'xi Province in northern China, was the largest city in the world in the seventh to the tenth century (Figure 3). It was rebuilt on the old Chang-an city of the Qing Dynasty (221–206 BC), which was severely damaged during the war. As the capital of the world's most powerful nation at that time, Chang-an city had a population of over one million and a walled area of over 8700 ha. The city's plan reflected the ideal city model defined in *Zhou-Li*: *Kao-gong-ji* in the Zhou Dynasty (see Figure 1): it had a well-organized grid street system with three gates on each side of the city walls, and it was divided into many functional zones for the royal family (palaces in the middle north), administration agencies and senior officials (south of the palaces), and residential and commercial uses with a hierarchical order. This model was duplicated in other capital cities in various China's dynasties, even copied in Japan while building Heiankyo City (Kyoto today), the capital of Japan then.

While Chang-an is a typical planned formal city, Ping-jiang city (Suzhou today) of the Song Dynasty (960–1279) is recognized as a typical planned informal city with a more free style. Ping-jiang was the economic hub of the Yangtze River Delta, China's richest area. The city had a walled area of 3.8 km × 4.2 km, and five city gates instead of the ideal model of 12 gates. On comparing Ping-jiang to Chang-an, one can find similarities as well as differences: the plan of Ping-jiang located the regional administration core (the governor's mansion as well) in the central area, the Temple of Confucius (the most important temple in the Chinese culture) to the south of the administration core, and mansions of rich families in the surrounding areas. The load network also had a grid pattern (Figure 4). However, the layout respected the topographic setting of the city, so it was cut by many canals and had only a total of five gates rather than the ideal model of three gates on each side of the city walls.

China's most important capital city is Beijing. The first walled city in Beijing was Ji, the capital of the State of Ji from the eleventh to seventh century BC, and later the capital of the State of Yan, one of the powers of China's Warring States period (473–221 BC). Beijing as the national capital as seen today was founded during the Yuan Dynasty (1279–1368), and functioned as China's capital through the Ming Dynasty (1368–1644), the Qing Dynasty (1644–1911), and the

Figure 3 Chang-an city, the planned capital of the Tang Dynasty (618–907). Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

Republic of China on the mainland. It is still the capital of the People's Republic of China. The plan of Beijing represents all characters of an ideal Chinese capital: a hierarchical space order, strictly defined functional zones, and a grid street network (Figures 5 and 6). Many features displayed in Chang-an city of the Tang Dynasty could be found in Beijing, such as the location of the Forbidden City (the Emperor's palace) in the middle north, and a well-defined hierarchical order of space and buildings (Figure 7).

Kevin Lynch identified the five 'elements of urban form' in Beijing: paths, edges, nodes, districts, and landmarks. His analysis indicates that Chinese cities in ancient and medieval periods were developed based on a sophisticated tradition with full planning skills (Figure 8).

Figure 4 A planned informal city: Ping-jiang (Suzhou) is a regional commercial hub in the Song Dynasty, AD 960. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

Urban Planning in China's Modern Times (Middle Qing Dynasty, 1840, to Republic of China in the Mainland, 1949)

As China was forced to open to the Western countries after the 1842 China–Britain Treaty, urban planning and city construction had two types of practices: in traditional Chinese cities and in cities with foreign concessions.

Traditional Chinese Cities

In cities where there were no colonial zones or foreign concessions, traditional planning principles were still honored. Most of those cities kept the traditional space order, and their townscape remained unchanged for hundreds of years due to lack of investment. In a few cities with new projects, planning activities were limited to infrastructure improvement and new

administration zones. Nanjing, the capital of the Republic of China in the late 1920s, was planned following the traditional Chinese space order and building form, even though the plan was made by planners and architects educated in the West (Figure 9). In general, not much change had occurred to the cityscape of traditional Chinese cities in the period from the 1840s to the 1940s, 100 years of chaos with endless wars.

Figure 9 A plan for the National Administration Center in Nanjing, 1929. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

Cities with Foreign-Occupied Concessions

After the Opium War of 1840, China was forced to open to the Western nations; concessions and colonial zones occupied and managed by western forces emerged in a number of cities along the east coast regions. The cityscape in these cities showed a coexistence feature of Western-style districts and traditional Chinese neighborhoods, similar to other colonial cities. Shanghai, the city opened to the West in the 1840s, had two urban areas: a Chinatown under the control of the Chinese government and several concessions managed by representatives of Western countries (Figure 10). The walled Chinatown kept a traditional Chinese form with an administration core in the center; outside the Chinatown, there were the British, French, and American concessions. These concessions were planned by Western civil engineers, surveyors, and architects with a Western space pattern different from the Chinese tradition. Through the planning of concessions, modern planning practice was introduced to China, especially planning regulations and the construction, maintenance, and management of infrastructure systems.

Chinese planners who graduated from West planning, engineering, and architecture programs participated in making Shanghai's master plans. From 1946 to 1949, three sets of master plans were completed. European planning theories and practice such as satellite towns and green belt system were applied (Figure 11).

Several Chinese cities were completely occupied by foreign forces as defined in treaties, such as Dalian in Liaoning Province and Qingdao in Shandong Province in the early 1900s. These cities were planned by architects and planners of foreign countries, so the plans reflected the culture and planning practice of the occupiers. The plan of Dalian occupied by Russia in 1900s, for instance, displayed a boulevard and plaza system common in European nations then (Figure 12). This pattern is quite different to the Chinese tradition; however, some Chinese rulers viewed the Western cityscape a symbol of 'modernization.'

Urban Planning in the People's Republic of China (1949 to Present)

The Soviet Model and the Anti-City Movement (1949–1978)

As China became a socialist country in 1949, a close relationship to the Soviet Union was established. Since then, planning in the People's Republic of China had a new meaning – not only in the physical development realm but also in economic and social development terms. The National Planning Committee and its local branches were in charge of all economic and physical development plans and projects through the Five Year Plan system. Every five years, a new Five Year Plan was issued by the National Planning Committee in which infrastructural, industrial, agricultural, and housing plans and projects from the national and regional to the local levels for the five years were described and arranged.

The Soviet-style planning system functioned for over 30 years until the 1978 reform era. Under the planned economy, the urban planning bureau in a municipality became an institutional tool to ensure the implementation of the national Five Year Plan and the municipality's local plans.

Figure 10 Map of Shanghai, 1915, showing areas under different administrations with a walled Chinatown at the south. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

Figure 11 Shanghai Master Plan, the first edition, 1946. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

There was little space left for local initiatives for economic and urban development. The planning system contributed to China's industrialization and urbanization with both positive and negative consequences. It helped the establishment of China's industrial base at the cost of low efficiency and a low urbanization level.

From 1959 to 1962 when a recession occurred, an antiurban policy was adopted, and a movement of forced urban–rural relocation to reduce pressure on urban services was promoted.

Figure 12 Plan for Dalian, the city center, 1900, by the Russian administration. Reproduced from Dong, J., 2004. History of City Building in China. China Architecture and Building Press.

The antiurban policy had its ideological roots since the Chinese communist revolution was essentially a peasant movement, and many leaders of the revolution had bias against cities.

Another controversial policy in the prereform age was the resident registration (Houkou) system that requires all urban residents to register at urban police stations, put in place in the 1950s aiming to control rural–urban migration and keep China's rural population in farm fields. The antiurban policy was at its peak during the political movement of the Culture Revolution from 1966 to 1976. Over 16 million urban residents, mostly young students, were relocated to the countryside, which caused a considerable reduction in the urban population in the period. In 1965, China's urbanization level (the percentage of registered urban residents in total population) reached 18%. However, 2 years later by the end of 1966, the first year of the Culture Revolution, the urbanization level dropped to 17.3%. Urban planning was viewed a useless or even harmful action, so all planning departments in cities were removed and all planning programs in universities were closed.

Since the 1978 reform, promoting urbanization by allowing rural–urban migration has become a national strategy aiming to stimulate economic growth. The 2010 census reports that 49.68% of China's total population was living in urban areas in 2010. The rapid increase of urban population means a huge demand for urban planning service in the postreform era.

Reform and Rapid Urbanization since the 1980s

The reform era beginning in 1978 opened a new page in China's history. The reforms constituted a fundamental paradigm shift from an ideology-led to an economy-led society and government. In general, the reform consists of two stages: reforming the agriculture sector in rural areas from 1978 to early 1980s followed by reforms in manufacturing and trading sectors in cities in the 1980–90s. With the implementation of the urban reforms, three main policies were formulated: introducing a market mechanism to replace the planned system in most economic realms, decentralizing decision-making power regarding urban development issues from the central to local government, and establishing urban land and housing markets. China's constitution has been revised several times to reflect the new foundation of the nation – a free market economically with an authoritarian government politically. For example, the 1988 constitution separates urban land ownership (state owned) from land-use right (a commodity), which lays the foundation for the property law in which a partial property right is created and protected.

The new policies ended much of the central planning authority in urban development issues with carrying out the decentralization oriented reform. Urban planning has become a local stake in negotiating with the central government in sharing revenue and making development decisions. According to China's Urban Plan Act of 1990, the master plan of a city, which is mandated by the Act, has to be approved by the provincial planning committee, and master plans of key cities such as Beijing, Shanghai, and Guangzhou have to be approved by the State Council. The central and provincial governments thus maintain their impacts over important development decisions via reviewing and approving master plans. At the city

level, plans not required for approval by the Act such as strategic plans, are made on behalf of local interest and used to guide local growth. The new institutional function of urban planning has brought a 'golden age' to the planning profession in China.

By introducing market forces – domestic and foreign investments as well as entrepreneur ideas – the reform created China's economic miracle and urban boom since the 1980s. The 1978 'Open door to outside world' reform was implemented at the early stage of the globalization era. It was historically a perfect timing. As Western investors and cross-national companies were looking for growth opportunities globally, an open China provided the ideal place due to its vast market potential, cheap labor, inexpensive land and energy, fewer regulations on environmental and labor protection, and, more importantly, a market-friendly government providing almost free infrastructure and favorable tax regulations. As the world's second largest economy, mainland China's gross domestic product reached $6717.2 billion in 2010 and its foreign reserve was $3.18 trillion by the end of 2011. China's economy had grown continuously at an average annual rate of nearly 10% from 1990 to 2010. Economic growth stimulates China's urbanization, and urbanization fosters economic growth. The strong economic performance lays the foundation for city construction and urban development. Urban planning has made its contribution to the economic miracle in fields of land acquisition and preparation, infrastructure development, and place making and selling at the global market.

China's urban population (831 million in 2008) is 2.7 times the total population of the United States (304 million in 2008) (Table 1). In 2007, China had two cities (Shanghai and Beijing) among the 20 largest cities in the world; the number will increase to four (the two already mentioned plus Guangzhou and Shenzhen) in 2025, according to the United Nations-Habitat predictions.

The urbanization process over the past 60 years has been especially fluid, although the main trend is a continuous urban population growth (Figure 13 and Table 2). Urbanization rates increased rapidly especially since the 1990s when China was becoming the 'world's manufacturing plant,' a by-product of the globalization process. Urban population increased by 18.2 million annually from 1995 to the 2000s, and the urbanization level reached 51.3% in 2011, the highest in China's history. The growth of the urban population has created a huge demand for new urban services on the urbanized land, which in turn has created an enormous demand for urban planners.

Table 1 Basic information about China's urbanization (2008)

Urban population			
Urban residents	*Migrants*	*Total population in urban area*	*Number of cities*
606 million (45.7% of total population)	225 million	831 million	655[a]

[a]Four state-administrated cities (Beijing, Shanghai, Tianjin, and Chongqing; a status similar to Washington DC in the United States) plus 651 other cities.

Figure 13 Trajectory of China's urbanization. Based on the National Statistics Bureau of China, 2004 (urban population refers to 'officially registered urban population' excluding migrants).

Given the increasing demand for urban housing, services, and jobs, urbanization has been officially employed as a means to promote economic growth. In a national debate in the 1990s about 'the importance of urbanization to China's economy,' supporters argued that urbanization had fallen behind China's industrialization and economic development so it should be encouraged. At that time, the central government adopted the policy of 'speeding up urbanization to stimulate economic growth' by promoting urbanization at a rate of 1.5–2% annually. In practice, expanding existing cities by creating new urban districts to absorb new factories and employees (migrants as majority) and reducing the amount of peasants by merging rural townships and villages ('che xiang bing cun') were the main strategies. From 1995 to 2002, the average urbanization level increased by 1.44% annually. Some Chinese scholars warn that given China's huge population baseline, the urbanization growth rate is too high to be sustainable. They suggest that an annual growth rate of 0.8%, or at most 1% will be more appropriate and rational.

The postreform urbanization has been facilitated not only by the government but also by the marketplace. Foreign and domestic investment in real estate and manufacturing stimulated the demand of urban land and urban labor. Most urban expansion or the so-called 'Chinese version of sprawl' has been a result of the establishment of suburban 'Economic Development Zones' (EDZs) where local government attracts foreign direct investment by providing low-priced land and free infrastructure. Researchers reported that 34–46% of urban land expansion was caused by the government-led land acquisition in EDZ. The immature land and housing market often fueled irrational land acquisition via large-scale land-use conversion from agriculture to urban uses. Urban planners also played a role in implementing the growth-oriented policy.

Stimulating Economic Growth in the Globalization Era through 'Place Making and Place Selling': The Task for China's Urban Planning Today

With the establishment of China's leading position in the world economy, both China's central government and several

city governments seek for the next development goal: stimulating economic growth and promoting Beijing, Shanghai, and several other well-developed Chinese cities to be international or global cities. Urban planning is expected to carry out the new task. The main approach of making an international city is through 'big international events' such as the 2008 Olympic Games in Beijing, the 2010 World Expo in Shanghai, and the 2011 Asian Games in Guangzhou.

In preparing for the 2008 Olympic Games, the Beijing municipal government under the leadership and financial support of the central government made and completed a bunch of plans including infrastructure development projects (building new and upgrading existing airports, subways, and expressways), constructing Olympic Games facilities (total of 31 sport fields and halls) and public buildings (the National Performing Art Center the China Central Television (CCTV) compound, and new museums and libraries), renovating historic buildings as well as preserved historic blocks, and building new commercial and office campus and housing projects (Figure 14). In Shanghai, similar strategies were adopted in preparing for the 2010 World Expo. Many innovative planning concepts were generated and implemented, including the application of ecofriendly technology (water and solid waste recycle and use of solar energy), reuse of old factory buildings for the Expo, integrating Expo facilities into city life after the Expo, and infrastructure improvement projects (Figures 15 and 16). Guangzhou followed the same development model in welcoming the 2011 Asian Games. In all cases, planners made significant contributions to these successful events and to promoting cities to be international hubs (Figure 17).

China's Urban Planning Profession and Planning Education Today (in the 2000s)

The Urban Planning Profession

From the 1930s to the 1940s, China had only a few planners; most of them were educated in the West, and the majority graduated from architecture or engineering schools. The old-generation planners laid the foundation for China's planning profession and planning education. Some of them participated in making master plans for Shanghai, Nanjing, and other key Chinese cities.

In the 1950s, before the divorce of China and the Soviet Union in 1960, a number of young planners got their planning training in Soviet universities. These planners played a critical role in China's early industrialization and urbanization under the planned economy. Their impacts on planning theory and practice, a mix of the classic European physical planning

principle and a centralized decision-making system, can still be found.

Today, over 110 000 planners of various levels are serving on city planning committees, working in planning bureaus and planning institutes. China has more urban planners than any other country. However, the number of planners per 1000 residents in China (0.008 planners for every 1000 residents) is slightly less than that of the United States (0.11 planners for every 1000 residents, total of about 33 000 American planners in 2010).

China established its certified planner system in 2000 with the help of the American Institute of Certified Planners (AICP), Royal Town Planning Institute, and Hong Kong Institute of Planning. Up to 2010, a total of 97 831 planners have taken the certification examination, and 14 928 have been awarded the 'National Certified Planner' status (CSUS and UPSC, 2010, 2011). The rate of passing the examination is much lower than that of the AICP examination.

New-generation Chinese planners are much better armed with planning knowledge and skills than ever before. Most of them are good at physical planning, urban design, geographical information systems, computer-assisted design, computer-generated modeling, and other software applications, but their training in the social science and public policy aspects of planning is still limited. In part this situation can be attributed to the demands on Chinese planners. Urban planning is still viewed as a profession handling infrastructure, city beautification, housing, etc. Social issues are not fully explored in the domain for planners. The situation is also due to China's developmental stage: to make a bigger pie is more important than to share the pie fairly. To a certain degree, underemphasis on social developments also is deeply rooted in Chinese history.

China's Urban Planning Education

Several Chinese universities offered urban planning courses in the 1930s, but none had independent planning programs; rather, most of the courses were offered in architecture or civil engineering departments, such as Tongji University and

Figure 16 Shanghai Pudong District. Photo by the author.

Figure 17 Bird's eye view of Guangzhou Zhujiang Newtown, 2010. Reproduced from Guangzhou City Planning Bureau, 2011. Urban Design in Guangzhou, China Architecture and Building Press.

Jiaotong University in Shanghai and Zhongyang University in Nanjing.

As China entered its industrialization period in the early 1950s, two universities, Tsinghua University in Beijing and Tongji University in Shanghai, established independent planning concentrations in their architecture departments. Five other universities followed this model soon after in the late 1950s. The seven urban planning programs educated Chinese planners for over 20 years in the prereform era. All of them were physical planning oriented, with limited coverage of social and economic development courses. In the 1980s, the first geography-based urban planning program was founded in Hangzhou University. Urban studies and regional economic development planning are the main topics for students studying planning in geography departments.

As more rural residents migrate to urban areas and the number of cities increases rapidly, the demand for urban planners is increasing considerably. The huge demand stimulates the growth of planning education programs. Since the 1990s, planning education programs have been established in almost all big Chinese cities. The number of planning programs increased from 28 in 1995 to 269 in 2011, with a total of 37 000 planning students enrolled, and 20 000 undergraduates, 4000 masters, and 300 PhDs graduating annually in recent years (CSUS and UPSC, 2011). In North America, the United States and Canada together had 99 planning educational programs in 2010. Thus, China becomes the country with the largest planning education capacity in the world (Figure 18).

China's urban planning programs have diverse backgrounds. Although most city planning departments are still within architecture or engineering colleges, about 35–40% of planning programs are housed in departments of geography,

Figure 18 Numbers of urban planning programs in Chinese universities vs. numbers of China's urban population (in 10 000) from 1952 to 2009. China's Urban Planning, Annual Report 2010, 2011, China Architecture and Building Press.

and one in the college of public administration (in Renmin University in Beijing). Because most demand is in physical development given China's rapid urbanization and huge urban population baseline, students with physical planning and urban design training are the majority and enjoy better job opportunities. Students of planning programs with urban studies background in geography departments do more work in research institutions and government planning agencies, but their job opportunities are less bright than that of design-oriented graduates. This fact reflects the nature of China's urban planning today: urban planning is more involved in physical development projects, and social development does not yet receive that much attention, although community planning is a growing area where many young planners are engaged with enthusiasm.

While the quantity of planning programs has been growing significantly, the quality of some programs is problematic. The Planning Accreditation Committee of China has only assessed and accredited 10% of all planning programs so far. It warned many newly established planning programs that they should take the quality issue more seriously since many of them are simply profit driven (CSUS and UPSC, 2010, 2011).

A positive development in terms of educational quality is that Chinese planning programs have been actively searching for partners in Western planning educational departments in order to exchange teaching experience and improve quality with the help of senior professors from well-known Western universities. Top Western and ethnic Chinese planning scholars from American and European universities are frequently invited to lecture in Chinese planning schools. This could be viewed as an important benefit from increasing international exchange in the globalization era.

Abstract

Public and private institutions or stakeholders use exhibitions and competitions as means of urban planning to stimulate the production and exchange of ideas and as tools to reshape urban form as well as governance. *Competitions* aim to elicit ideas from various people – mostly professionals, but occasionally also the general public – on a defined topic, including urban plans. *Exhibitions*, both educational and exemplary, provide spaces respectively for the comparison of architectural and urban representations or actual construction. Both methods have long histories of changing the goals and themes that have evolved with the shifting definition of the profession.

Urban planning – defined as a complex and multifaceted attempt to adapt the form and function of a city to the multiple needs of its various stakeholders and as a tool to effect political, social, and physical change – deploys a broad range of methods to reshape urban form, including *competitions* and *exhibitions*. Both tools permit the comparison of projects and built designs from a variety of contributors, who often come from other cultures and different places. They aim to enhance good design and to prompt public discussion and awareness, even consensus. Urban planning or urban design competitions have a long history that is rooted notably in the French architectural education and German design tradition. Since the turn of the nineteenth century, urban competitions and (educational as well as exemplary) exhibitions helped define the emerging profession. Competitions and exhibitions also give visibility to a specific city and help brand a location; public and private organizers around the world thus consider competitions and exhibitions to be important tools in positioning cities and regions in the global marketplace. Both originally emerged in Europe and have spread throughout the world, where various parties have tested them in different cultural contexts. Their focus has also evolved, from being primarily focused on aesthetics and top-down approaches to addressing functional concerns or issues such as environmental sustainability, and they have come to include the bottom-up involvement of citizens (for general literature, see Speiregen, 1979; Omi, 1986; Haan et al., 1988; Becker, 1992; Jong and Mattie, 1994; Aymone, 2007).

Competitions

A planning competition is only one of several options available to an organizer when choosing an urban plan and a planner. Others include directly commissioning an individual to come up with a plan, holding planning workshops or seminars, and appointing a planning committee or a consultant to make the decision. If the topic and its constraints are clearly defined so that the participants can make meaningful statements within a limited period of time, and if the political and administrative contexts and the economic situation permit consequent implementation or adaptation of the results, competitions are good ways to find solutions. Competitions allow the sponsor to select from a variety of proposals, even if the organizer decides not to implement the proposal as such or to use only some ideas, as the competition may help to stimulate further insights into the planning problem and ideas for responding to it.

Such competitions can take several forms. They can be open to the general public, restricted to members of the relevant professional institute, or restricted even further to a limited number of participants, whether appointed by the organizer or chosen after an application process. (These procedures may also follow upon each other, and restricted competitions can include payment to participants.) Restricted competitions have been criticized for being limited to famous names or big companies. In contrast, critics note, anonymous and open competitions allow unknown and young planners to participate and present their ideas, and may result in new concepts. This can, however, mean large numbers of participants, or lead to the choice of an author who lacks the means and experience to realize the proposal. As only prizewinners are paid, much unpaid work is done, particularly in the case of complex urban competitions, which, therefore, are sometimes considered to be unproductive. Nonetheless, even unbuilt contributions are part of the architectural culture and history of a city and a period. In some cases, unrealized competition projects have had a stronger impact on planning history and theory than built ones. Peter and Alison Smithson's entry in the 1958 urban planning idea competition 'Capital Berlin,' featuring a platform over the city, serves as an example: never built, it nonetheless inspired projects and debates internationally.

Cities and nations around the world see competitions as a particularly useful way to include citizens in the decision-making process, and also as a way to justify their planning choices and expenses. In turn, the democratic character of a competition depends primarily on whether its preparation and ensuing realization are part of a public and open discussion. The process of a competition per se is apolitical, and any political system can use one as a purely technical device to identify the most appropriate response, as the Soviet government did in holding an international competition for plans for Greater Moscow in 1931–32. More generally, the outcome of a competition depends on the participants and is strongly influenced by the aims and quality of the competition brief and the organizers. The institutional character of the organizers – whether they are public institutions, private sponsors,

professional organizations, architectural schools, or magazines – and the level of their concrete power over the competition site determine whether the competition leads to realization or is limited to creating ideas, and whether it is supposed to adapt to the existing context or provide a long-term vision for the future.

Preparatory groups – mostly professionals and functionaries – make major decisions on the overall distribution of functions in a city, and on the use, size, and form of an urban plan. They prepare a set of competition documents that can range from primarily descriptive to very precise and technically detailed. These documents might include concept plans, maps, and data on the socioeconomic structure of the population; requirements for educational, housing, leisure, or infrastructure equipment; and general guidelines on urban function, structure, and form. The preparatory documents might end up guiding future development, whether or not the competition produces a winning project that the city implements.

History of Major Large-Scale and City Center Competitions

Architectural competitions have been held for many centuries, particularly for the design of religious and public buildings. Competitions for entire cities or urban areas also have a long history. An early example is the one held after the London fire of 1666, as well as the international idea competitions for urban embellishment opened by the Russian empress Catherine II for the city of Saint Petersburg (1763) or the contests for the Place Louis XV (today's Place de la Concorde) in Paris (1748).

Urban planning was usually seen as a part of architecture, and the competitions held by professional and educational architectural institutes included urban design projects, such as for a 'Seaside Resort for a Sovereign on the Mediterranean Coast,' a topic at the Paris Ecole des Beaux Arts in 1872. Educational institutions held student competitions for grading and awards such as the 'Rome prize,' which included travel and a several-year stay in Rome. These projects were not intended to be built, but nevertheless reflected the design spirit of their time. The 'Rome prize' winners were assured an honored part in public building projects on their return. With their long history of academic competitions, French planners won late early twentieth-century international competitions for the enlargement of Barcelona (1903), Bucharest (1906), Guayaquil (Ecuador) (1907), Antwerp (1910), Yass-Canberra (1911) (Australia), and other cities in North and South America as well as in France itself (Risler, 1915).

The history of urban competitions reflects the development of the planning profession: following industrialization and rapid urban growth, early competitions tackled large areas on the outskirts of a city or even a whole city. With the growing scale and complexity of cities, their parts and compounds became the main topic of later competitions. In spite of the large number of competitions held over the last century, some of the earliest major transformations and extensions of cities, including the work of Eugène Haussmann in Paris (1850s–70s) and the extension of Berlin under James Hobrecht (1862), were based on direct commissions or procedures other than competitions.

A comprehensive and international analysis of urban planning competitions is still lacking, and the number of competitions is too large to be analyzed here: analysis of the late 1920s, for example, shows between 15 and 30 urban planning competitions annually in Germany alone (Becker, 1992). But a brief genealogy of major examples, presented here in chronological order, shows overall trends.

One of the most interesting examples of nineteenth-century urban planning, the transformation of the Vienna fortification zone, did result from an international urban competition in 1857–58 (Albers, 1997; Hall, 1997); it requested ideas for traffic planning, plot division, and urban beauty for a zone both sides of which were already built. None of the prize-winning or recommended designs was realized, but the city used them as references for a basic urban plan. In 1892, Vienna was once again the site of a major urban competition; this one, like the competition for Munich in the same year, invited ideas for a master plan of the whole city. These two competitions can be seen as milestones marking the early development of urban planning – intimately connected to the works of major urban planning theoreticians of that time, such as Reinhard Baumeister, Camillo Sitte, and Josef Stübben, whose theoretical work inspired the implementation of the later master plan for Vienna (Herscher, 2003).

Some famous urban designs included competitions as one part of their complex history. The mid-nineteenth-century extension plan for Barcelona resulted from conflict between the liberal central government and the conservative communal government. Initially, several plans were on the table, including a large grid expansion by Ildefons Cerdà. But the commune supported a small-scale project, and sponsored a competition in 1859. Antoni Rovira i Trias won with a proposal for a star-shaped extension of the city's historic core. The national government rejected this proposal and reverted to Cerdà's plan.

A milestone in urban planning history was the Berlin competition of 1908–10. Initiated by architects' associations and organized by several independent municipalities, it concerned a large urbanized area of more than 5 million inhabitants. Although the two winning proposals were not realized as such, the process helped clarify major problems and led to several competitions for smaller parts of the city. Through exhibitions, publications in magazines, and private brochures, the city disseminated the competition formula and its results. They became important references for other cities and planners, stimulating other large-scale competitions in major and minor European cities in the late nineteenth and early twentieth centuries, including Gothenburg (1861), Strasbourg (1877), Krakow (1910), Reval (1913), Dublin (1917), Paris (1919), Budapest (1936), and Zagreb (1929) (Albers, 1997). Some planners, including the Frenchman Léon Jaussely, participated in several of them (Albers, 1997).

In Europe, early competitions concentrated on remodeling and enlarging existing cities. Meanwhile, new nations around the world sought cultural representation, and they planned and constructed entirely new capital cities. Competitions held for Canberra in 1911–12 (winner: Walter Burley Griffin) and for Brasilia in 1956–57 allowed Australia and Brazil, respectively, to obtain a state-of-the-art urban plan ready to impress the nation and foreign countries. The winning project for Brasilia's master plan, by Lucio Costa, was successful in not only laying out a comprehensive plan but also establishing a foundation myth for the new capital (Holston, 1989). Following another international competition in 1977, an

American team, International Planning Associates, won the prize of developing the master plan for the new federal capital of Nigeria, Abuja. Such competitions gave government authorities the opportunity to consult with leading planners and, as in the case of Canberra and Abuja, eventually appoint foreigners to realize the plan.

Even in densely built Europe, governments held competitions for new towns. Italy, under Benito Mussolini, reclaimed marshland and then sponsored a series of competitions to build new cities on it, including Sabaudia; the regime thus demonstrated its capacity to provide housing for its growing urban population. Great Britain and Germany held competitions for new towns, designed according to modernist planning principles in the post–World War II period to create new population centers. Examples include Aarne Ervi's winning proposal for the center of the new town of Tapiola in Espoo City, Finland, announced in 1953; a competition for the central area of the new town of Ashdod, Israel, in 1965; and Richard Llewelyn-Davies's prize-winning entry to the 1967 competition for Milton Keynes, a new town in northern England, with a decentralized, car-friendly, low-density, and flexible design.

European institutions, regions, cities, and architectural schools sponsored city competitions and projects for new cities, all in a quest to build a capital for newly unifying Europe; but these competitions were, generally, flawed by the sponsors' lack of political and financial power, the dominance of nationalism, as well as the unclear future of the new European communities. Furthermore, such competitions demonstrated the difficulty of defining Europe. In the competition sponsored in 1954 by the Saarland – a region that considered a European future to be a welcome escape from both integration into France and the impossibility of a return to Germany – the jury selected three winning projects, so different from each other that none could represent a common Europe (Hein, 2004).

Reconstruction after World War II stimulated urban competitions of various scales in several countries, leading to intense and often controversial discussions. The German city of Nürnberg made a great effort to involve citizens, opening one idea competition to all citizens (yielding some 1192 proposals) and another one to planning professionals. The latter competition proved so successful that it also sparked the German Building Exhibition of 1949, which attracted some 300 000 visitors and helped rebrand the city of the Nazi Party gatherings and of the Nürnberg trials as a modern and democratic center (Diefenbacher and Henkel, 2009). Meanwhile, the most political of the large-scale competitions was probably the international urban idea competition for 'Capital Berlin' of 1957–58 (Hein, 1991), organized by the West German and West Berlin governments, which targeted an area in the city center that was largely under East German administration – a provocation to which the East German government reacted with a competition of its own.

In contrast, the competition for rebuilding the atom-bombed center of Hiroshima was a unique case among the more than 200 cities that had been bombed in the war. Japan had no previous experience with warfare on its land, with postwar rebuilding, or even with competitions. A confluence of several elements in 1948 led to the unusual building of Hiroshima Peace Park: international interest, a special law providing supplementary funding (the Peace City Law), a comprehensive project chosen by competition, and a sensitive architect. The government had dispatched Kenzô Tange in 1947 to draw the land use plan for Hiroshima; his prizewinning project for the Peace Park established connections with the immediate surroundings and even projected a network of related facilities for other areas of the city. Reaching beyond the Nakajima neighborhood, it visually integrated the A-Bomb Dome with the remainder of the Hiroshima Industry Promotion Hall (a brick-and-steel building located close to the center of the explosion), while also integrating urban design, architecture, and landscaping (Hein, 2002).

Other large-scale competitions held in the wake of natural disasters highlight the global approach of urban planning in the postwar era. After an earthquake destroyed the Macedonian city-capital Skopje, the Yugoslav government established a group of international consultants who chose an outline plan by Doxiadis Associates and the Polish architect Adolf Ciborowski (who had supervised the rebuilding of Warsaw). In 1965, the country held an international competition for a design to rebuild the city center: the consultants invited four Yugoslav firms, as well Van den Broek en Bakema (Netherlands), Maurice Rotival (United States), Luigi Piccinato (Italy), and the first-prize winner, Kenzô Tange (Japan).

One engine for the global spread of competitions was colonialism: European countries brought the practice of holding competitions to their colonies. These continued the practice even after independence as a sign of modernization and emancipation. One example is the international competition held in 1961 for the piercing of the citadel, the casbah, of the capital city of Tunis. The consequent period of increased globalization has contributed to the growing number of international competitions since the 1970s, as can be seen in the listing of those approved by the Union Internationale des Architectes (UIA). Standouts among these in the early years were student competitions in the field of housing, sponsored by the Institut National du Logement Belge (INL) or by the UIA. By the 1980s, the number of competitions proposed by non-European institutions started to increase, including one in the United Arab Emirates for plans for the University of El Ain (won by SWECO-AS (Sweden)) in 1983 and another in Kuwait for the proposal for a city on the sea, the Pearls of Kuwait, won by P. Cox, Richardson & Taylor (Australia) and Jerde Partnership (United States) in 1989 (www.uia-architectes.org).

By the 1990s, competitions were a common tool around the world for a city or other body to gain international advice and attention. In 1996, Bucharest sponsored an international competition for proposals to transform its center both to host the offices of the capital city and to celebrate the year 2000. Out of 235 projects from 33 countries, the jury invited 15 authors to continue their research in a second phase; it finally awarded the first prize to Meinhard von Gerkan and Joachim Zeiss (Germany). The number of competitions has grown over the years, with the locations sponsoring them spreading out even further around the world and bringing together international juries and international participants, such as the 2003 competition for the Freedom Park Trust in South Africa, where three finalists from various parts of the world were honored (US firm Obra Architects, Tai Fai of Hong Kong, and Vladimir Djurovic Landscape Architecture in collaboration with the architect Imad Gemayel of Lebanon); or the 2004 idea

competition for the Place des Martyrs and the Grand Axis of Beirut, won by a group from Greece.

The 1990s also saw planning competitions on regional scales, often with a focus on infrastructure. In May 1990, the cities of Strasbourg, France, and Kehl, Germany, opened a competition for ideas for a border-crossing district along a proposed new highway. Connecting Strasbourg to the German high-speed road network, the highway would help revive the neglected 300 hectare Fronts de Neudorf area. With urban planning departments from two different nations, the project was European rather than national. The departments tried to coordinate their local planning laws and to create a concrete example of collaboration among regions of different European Union (EU) member states and between former enemies. Their success spurred further cross-border competitions.

As planning doctrines and urban needs shift, so do the foci of competitions. In recent years, environmental sustainability has become a prominent guideline. In 2007, the French president announced a competition on the future of Greater Paris in the next several decades. The theme was that the reduction of greenhouse gases, agreed upon in the Kyoto Treaty, and the larger societal changes needed to preserve energy, should all start in cities. The president invited architects to rethink Paris' urban spaces to develop a more ecological way of life and to integrate the center and the periphery; he imagined a new global development plan that would resolve the tension between rapid and uncontrollable development, on the one hand, and the need to preserve energy and create an ecological equilibrium, on the other. The competition itself and the underlying presumptions have since raised numerous questions and provoked a flurry of responses in the media and among academics. However, in terms of realization, very little has ensued.

Competitions for Limited Areas and Special Functions

Planning an entire city area brings with it numerous difficulties and demands extensive knowledge that cannot be expected from competition participants. Simultaneously with the long and rich history of competitions for large-scale designs for new cities, which was mapped in Section History of Major Large-scale and City Center Competitions, public and private sponsors also opened competitions for limited areas and clearly defined tasks such as campuses, government centers, commercial or recreational centers, and urban parks. Examples can be found worldwide: a privately sponsored competition for the University of California (1897–99), city-held competitions for educational districts in Tokyo (1940s), design competitions for civic centers in the United States, and the urban design competition for the government districts in the Spreebogen and Spreeinsel areas in Berlin (1993–94).

It is likely that the largest number of competitions has been organized for residential layouts. Examples can be found in various countries; examples from Germany are given here for illustration. The country has been a major organizer of competitions over the last century, and their topics and results reflect the main concerns of housing over this period. Early competitions focused on small-city and company housing, such as for the Krupp colony Altenhof in Essen (1892). Metropolitan housing, economic land use, and the creation of a rational block structure became central topics in the competitions of 1911 for Tempelhofer Feld and Schöneberg South that followed the Greater Berlin competition of 1910. The search for an economical solution for residential areas climaxed in competitions for the experimental district Berlin-Haselhorst (1928) and the Dammerstock-Siedlung in Karlsruhe (1929).

The French tradition of student competitions continues to influence contemporary events. The French Programme d'Architecture Nouvelle (PAN) invited students to improve the quality of subsidized housing between 1972 and 1987, awarding the prize winner the opportunity to realize his or her project. Building on this, Europan is a student competition in which municipalities propose some 50–70 strategic sites in each session, asking students to solve spatial problems in urban contexts and to formulate new urban paradigms and sustainable strategies (http://www.europan-europe.eu).

Federal and municipal governments in the United States have also sponsored some notable targeted design competitions. The World Trade Center site in New York saw a design competition in 2002, and the redesign of the Highline in New York is the outcome of a 2004 competition launched by the Friends of the Highline and the City of New York. Recent examples include a competition for a new mixed-income housing model opened by the Chicago Housing Authority (with the City of Chicago and the US National Endowment for the Arts), awarded to Brian Healy Architects of Boston; the Congress for New Urbanism's AuthentiCITY open design competition for West Palm Beach, Florida, in 2012; and the ONE Prize 2012, a competition that asks entrants to explore the regenerative possibilities of urban transformation in the struggling US economy. Several of these events exemplify the opportunity that competitions have to inspire societal change (http://www.dexigner.com/news/25074). Nonetheless, the US sponsors far fewer competitions than other countries.

More recently, China has emerged as a major player in the practice of holding competitions for targeted urban design. In conjunction with the creation of the new Yangshan deep-water port, the Shanghai municipal government held an urban planning competition in 2002 and selected a Hamburg-based design firm, Von Gerkan, Marg und Partner Architects, to design New City for 800 000 people as one of 11 new satellite towns of Shanghai (Gerkan, 2008). Other recent examples include a 2002 competition for an art, cultural, and entertainment district in West Kowloon (awarded to Foster and Partners); the Quanzhou Luoyang River Urban Design Competition (2011); the Pingdongshan Baigui Lake Urban Design Competition (2011) and the Hangzhou Bay New Town Competition (2010). These competitions attract participants from around the world.

Exhibitions

Exhibitions are an important way for cities and other bodies to present urban planning theories, concepts, and realities to specialists and the general public. They can follow on competitions or accompany conferences but can also be events on their own. Their purpose and impact are multifold and have shifted over time. They can serve as a tool to experiment with

and spread new concepts to an international as well as local, professional, and lay public. They may serve as a focus for decision makers and citizens and can also attract funding or help to focus it. Media attention lavished on these events can contribute to a city's brand and promote its position in the urban hierarchy.

Among the multiple forms of exhibitions, two forms can be broadly distinguished: educational, such as the public presentation of historic or contemporary projects, plans, and models for concrete or visionary proposals (often organized in conjunction with specialist conferences) in one locale or as a traveling exhibition; or exemplary, such as the building or rebuilding of an urban area with temporary or permanent buildings, as a specific urban design project or as part of another event such as a world's fair. Both are part of the planning process of many countries that aim to promote democratic participation, and they can go hand in hand. Both can also be primarily cultural events, displaying the history, present, or future of planning and helping to promote an area economically. And both have increased over the last decades together with the proliferation of visionary and unbuildable projects and the creation of architectural institutions. The following proposes a chronological overview of select examples.

Major educational exhibitions focusing specifically on urban planning have been held since the turn of the nineteenth century, reflecting ongoing debates in the emerging profession. In 1903, Dresden was the site of the first German Municipal Exhibition (Erste Deutsche Städte-Ausstellung), which showcased the achievements in engineering and urban planning of several German cities. In 1911, an exhibition on hygiene was held in the same city, and included a large display on urban planning. The theme of overcrowding was at the center of the tenement exhibitions organized by Lawrence Veiller in 1899 and 1900 in New York. City planning became a focus of the work of Benjamin Marsh; his 1908 exhibition 'Congestion of Population in New York' led to his 1909 publication *An Introduction to City Planning*, as well as municipal activity (Commission on Congestion of Population (1911); Veiller, 1900–1901). Other exhibitions were held to promote new urban plans, such as the McMillan Plan for Washington in 1902 or Daniel Burnham's plan for Chicago sponsored by the Commercial Club of Chicago in 1909. Yet others occurred in parallel with congresses of the International Garden City and Town Planning Association or with international architectural congresses, such as that of London in 1906, which displayed works of major planners, including Raymond Unwin, Josef Stübben, Charles Buls, and Eugène Hénard (Meller, 1995).

Exhibitions held in Berlin and London in 1910 were key events in urban planning history. Featuring projects from numerous countries, they aimed to convey political, cultural, and aesthetic statements. The London exhibition was held in conjunction with an international conference on town planning, which had an impact as far away as Japan and included the first elements of Patrick Geddes's 'Cities and Town Planning Exhibition.' Major publications by Werner Hegemann based on the exhibitions of Berlin (1910), Düsseldorf (1912), and Gothenburg (1923) (Hegemann, 1913, 1925) expanded the range of those exhibitions' impact. Enthusiasm for urban planning was on the rise. Three major urban planning exhibitions were held in 1913 alone: in Nancy, Ghent, and New York. Other exhibitions followed even in national realms, including in Australia, the United Kingdom, and the United States (Freestone and Amati, 2014). Town planner and urban theorist Patrick Geddes expressed a common sentiment when he praised exhibitions for modifying the civic atmosphere:

> "In each city the Town Planning Exhibition has effected, more or less, this education of public opinion, and with practical results. Sometimes this impulse is a diffused one, as in Edinburgh, with results manifold, but not easily separately traced. Sometimes there are immediate definite results to which we can point, as in Dublin: e.g. (a) formation of a "Cities and Town Planning Department" of the National Museum, (b) formation of a "Town Planning Association of Ireland," with (c) immediate initiatives of practical Improvements in Dublin itself." (Geddes, 1913)

Geddes's exhibition on 'City and Town Planning' was sent to India and started a major trend of traveling shows – a means to bring the concept of planning to a broad group of people.

Other planning exhibitions followed, and for some institutions, notably the New York Museum of Modern Art (MoMA), traveling exhibitions became a major instrument in spreading planning ideas within the United States and beyond. Starting with the 1932 exhibition 'Modern Architecture: International Exhibition,' which included a section on *Siedlungen*-type community housing, select members and associated advisors of the institution used exhibitions to translate European modernist planning into American practice. From the 1930s onward, exhibitions were often inspired by modernist planning ideas, local problems, and the desire for public involvement: the 'Coventry of Tomorrow' exhibition in 1939; the Rebuilding Britain Exhibition of 1943; or New York MoMA's circulating 1944 exhibition 'Look at Your Neighborhood,' which was designed by Rudolf Mock (with support from Clarence Stein) to educate the American public on the need for comprehensive postwar urban planning (Mock, 1945).

The need for adequate housing for workers during the war, the wartime experience with planning as a helpful tool for organizing large spaces, and the looming car-based sprawl of postwar cities spurred calls for comprehensive planning and for intense reflection on the peacetime future of cities, whether war destroyed or not. The reconstruction exhibition 'Berlin Planterster Bericht' of 1946 highlights attempts to redefine Berlin's urban area even beyond the war-ravaged areas. Many other rebuilding exhibitions followed, notably in the war-damaged German cities (Petz, 2010). Many municipalities around the world held planning exhibitions to introduce their population to new urban concepts. Edmund Bacon, who headed the Philadelphia City Planning Commission from 1949 to 1970, organized the 1947 Better Philadelphia Exhibition that laid the groundwork for the postwar transformation of the city. The exhibition attracted some 385 000 people; and the pamphlet accompanying the exhibition tried to convince the general public of the need for comprehensive urban transformation.

Exhibitions continued to be places to imagine the future as the approach to urban planning changed in the 1960s. MoMA's 1967 exhibition 'The New City: Architecture and Urban

Renewal' promoted rational land development, integrated transportation, citizen participation, neighborhoods with public facilities, and housing with the goal of economic development in search of a new 'wholesome urban environment,' in the words of Sidney J. Frigand, the former deputy executive director of the New York City Planning Commission (Museum of Modern Art, 1967: p. 7). Many of the projects in the show were just as heavy-handed, but his words showed a changing approach to urban form and life. The exhibition was not limited to documenting the past or proposing abstract solutions; it intervened in the future of New York with very specific design proposals by several teams, including one from Cornell led by Colin Rowe and Thomas Schumacher.

In recent decades, architectural museums and archives have sponsored a variety of exhibitions on planning in different periods, making them instruments for the promotion of particular concepts or styles. At times, these institutions intervene in planning, as was the case with the 'Berlin Morgen' exhibition in Frankfurt am Main in 1991, where proposals later reappeared as competition entries (Lampugnani and Mönninger, 1991). Other exhibitions concentrate on historic plans: 'La Ville. Art et Architecture en Europe 1870–1993' (1994), held at the Center Pompidou in Paris and later staged in Tokyo, provided both the general and the professional public with detailed insights into cross-cultural planning. Traveling exhibitions of printed boards and models can reach people around the globe, on themes such as the rebuilding of the Tohoku Region in Japan after the 2011 tsunami and the Fukushima reactor disaster.

Exemplary exhibitions also take built form, whether provisional or permanent. Such displays are a means to try out visions, promote urban concepts, or display recent achievements. World's fairs have concretely featured urban forms. The American world's fairs in Chicago (1893) and St. Louis (1904) were temporary manifestations of City Beautiful concepts and helped to popularize the new style. The New York World's Fairs in 1939 and 1964 helped promote the concepts of the motorized city of the future. More recent events include those in New Orleans in 1984, Tsukuba in 1985, Vancouver in 1986, Brisbane in 1988, Seville in 1992, Lisbon in 1998, Hanover in 2000, Zaragoza in 2008, Shanghai in 2010, and Yeosu, South Korea, in 2012, with the most recent ones focusing on issues of urban sustainability.

World's fairs have also been the locus for the display of urban transformations as embodied in large-scale urban models. Models of the Liverpool docks and Hamburg's harbor, for example, were displayed respectively at the world's fair in London in 1851 and Paris in 1900 to showcase and promote these locations. Le Corbusier displayed his vision of a modern Paris in 1925 in the Pavillon de l'Esprit Nouveau at the Exposition international des Arts Décoratifs et modernes. The 1939 New York World's Fair displayed a giant model of the city of the future, sponsored by General Motors. The Shanghai Urban Planning Exhibition Center with its huge model of current and approved buildings continues this tradition.

Exemplary exhibitions have created a range of permanent urban elements, transport infrastructure, riverfront redevelopment, parks, or housing. Housing has been a focus for several international building exhibitions, the most famous of them in Germany, where the form and function of residential design in each epoch were represented through its own exhibition. Examples included the artists' colony at Mathildenhöhe near Darmstadt (1901), the 1925 Stuttgart exhibition entitled 'Die Wohnung,' modernist projects such as the Dammerstock mentioned in this article, or the 'traditionalist' Stuttgart-Kochenhof Siedlung (1933) (Cramer and Gutschow, 1984). Many building exhibitions showcasing urban design and housing accompanied rebuilding after World War II in numerous German cities, including Nürnberg, München, and Hamburg. Among the most influential ones are the Constructa (1951) in Hanover, which aimed to lay out principles for reconstruction, and the Interbau Berlin (1957) that featured the reconstruction of an inner-city district as a high-rise housing area, the Hansaviertel.

Germany has continued the practice of building exhibitions in recent decades with several innovative events, including the International Building Exhibition (IBA) in Berlin of the 1980s, which aimed at a critical reconstruction of the city and inspired the Kumamoto Artpolis of the 1990s in southern Japan (a building exhibition transformed into a traveling exhibition that toured the world); and the International Building Exhibition Emscher Park in the Ruhr region (1989–99), which aimed at setting transformational impulses for an old industrial area (Shaw, 2002). The Hannover 2000 Expo became the flagship for a combination of world's fairs, model planning, and housing exhibition. There, an overall city regeneration plan included 2000 housing units built to respond to environmental and social sustainability concerns. The IBA Hamburg (2013) and other concurrent events continue this tradition into the present (e.g., the Netzwerk 'IBA Meets IBA') (Hamburg, 2010).

The German concept of building exhibitions has found international interest. Numerous cities elsewhere have undertaken housing regeneration expos such as Bo97 in Staffanstop (Sweden, 1997), and Glasgow's Homes for the Future Housing Expo (1999), Malmö (2001), and Stockholm (2002) continued this tradition. The trinational exhibition, the IBA Basel 2020, may be an indication of further internationalization of the concept. Exemplary exhibitions are extremely costly and time-consuming, and they require broad participation; they do, however, help to create larger interest in urban development issues – bringing together socioeconomic and physical development issues, providing an innovative instrument to flexibly address large-scale problems within a broad framework, allowing the mobilization and focusing of resources, developing paradigmatic examples, and possibly becoming models for collaboration among various urban stakeholders (Hamburg, 2010). The insertion of viewing platforms and information pavilions as part of large-scale urban transformations such as that of the HafenCity in Hamburg, or institutions such as the Shanghai Urban Planning Exhibition Center, build on the success of exemplary exhibitions and make entire areas of cities effectively an exhibition site.

A Cultural Phenomenon

Over the last century, competitions and exhibitions have been important tools in the spread of urban theories, concepts, ideas, and planning practices. They have not only echoed the development of modern planning but also furthered it through

the promotion of exchange, particularly between European countries and North America, since the beginning of the profession at the turn of the nineteenth century when there were no examples to follow. They were helpful tools in cities' and planners' search for the best functional and aesthetic solutions. They have been a tool in cultural transfer and have contributed to the development of the discipline and of building culture.

There are, however, cultural differences in the historical and contemporary use of these instruments. Germany has a long tradition of public competitions and exhibitions. France's competitions and exhibitions have been sustained not only by the public but also by architectural schools. Both countries continue to promote these tools. Other countries, such as Japan, with different planning traditions and different aims have held only a limited number of competitions, and those have had limited impact. Instead, these countries developed other approaches for the selection of urban design projects. Japan, for example, historically preferred to invite foreign experts, send planners on study trips, and introduce foreign projects and ideas in magazines or book translations. Direct commissioning continues to be highly valued.

Over the last century, competitions and exhibitions have become an important tool for urban transformation. The increased desire for urban marketing and branding emphasizes their importance for the major stakeholders in the city. Most surprising among the current promoters may be China, with its current flurry of competitions and exhibitions bringing together practitioners from around the world.

Urban Planning: Methods and Technologies

Richard E Klosterman, What if?, Inc., Hudson, OH, USA

Abstract

The collection, analysis, and dissemination of the information needed to improve public and private decision making is one of the major justifications for urban planning. As a result, planning methods and technologies have played a central role in planning practice and education since the profession's inception over 100 years ago. This article reviews the evolution of planning methods and techniques, considers the most important technologies used in contemporary planning practice, and speculates on the future of planning methods and technologies.

Evolution of Planning Methods and Technologies

Three relatively distinct eras can be traced in the evolution of planning practice, methods, and techniques. The first era, 'planning as design, characterized planning from its inception until the 1960s. The second, 'planning as applied science, characterized the profession in the 1960s and 1970s. The third, 'planning as communication, has characterized the profession since the 1980s. The following sections examine each of these eras and their corresponding methods and technologies in turn.

Planning as Design

The planning profession in the United States emerged at the beginning of the twentieth century in response to the unregulated urban growth and inadequate public facilities of the new industrial city. Guided by a rather naive form of environmental determinism, the early planners assumed a professional responsibility for improving society through changes in the physical environment and protecting an overarching public interest from the presumably self-interested and uninformed actions of elected officials and private citizens. Planners' methods were largely intuitive methods of manual design adapted from the profession's institutional homes in architecture and landscape architecture, taught primarily by planning practitioners in the ubiquitous studio workshop.

By the 1950s, these largely intuitive methods had evolved into a standard land use planning approach codified in F. Stuart Chapin's *Urban Land Use Planning* (Chapin, 1957) and T.J. Kent's *The Urban General Plan* (Kent, 1964). This model defined planning as the preparation of a formal document laying out a long-term, comprehensive, and general vision for a community's future physical development, including public and private uses of land and related public facilities. These plans included a summary of existing and emerging conditions and needs, a statement of planning goals, a 20- or 30-year development plan expressed in map form, and policies for implementing the plan. This conception of planning continues to dominate planning education and practice, as reflected in the fifth edition of Chapin's text (Berke et al., 2006).

Planning as an Applied Science

The planning profession's attention turned in the 1960s from the design of the physical city to new concerns with improving transportation access, reducing urban blight, and improving social and economic conditions at the urban and regional scales. The dominant perception of the field changed from an image of 'planning as design' to 'planning as an applied science' as new students, faculties, and departments joined the profession from outside the traditional schools of design. An increased emphasis on quantitative methods and social science theory led to the abandonment of the once ubiquitous design studio for new courses in research design, statistics, and quantitative techniques utilizing texts such as Isard's monumental *Methods of Regional Analysis* (Isard et al., 1960) and Krueckeberg and Silvers' *Urban Planning Analysis* (Krueckeberg and Silvers, 1974). Planners' professional role was now seen as delivering unbiased, 'objective, and politically neutral advice to elected officials and the public and collecting and disseminating more and better information that could inform and improve the policy-making process.

Computers first began to be used in planning in the 1960s, as part of a general faith in science and technology and the emergence of new academic fields such as operations research, urban economics, and regional science. The most notable early attempts to use computers in planning were the ambitious and highly visible federally funded efforts to build large-scale metropolitan land use – transportation models and integrated municipal information systems. These efforts were seen as providing the foundations for a new 'science' of planning by helping planners understand and guide the urban development process and improve the information base for public and private decision making (Harris, 1965; Webber, 1965).

Planners' optimistic faith in computer technology was severely tested in the 1970s. The pioneering efforts to develop large-scale urban models and municipal information systems failed spectacularly, largely as a result of their overly ambitious goals, the limitations of available computer equipment, and the lack of required data. Sophisticated analytic tools such as mathematical programing which were assumed to provide the foundations for 'scientific planning' were found to be largely inappropriate for planners' 'wicked problems' which are hard to define or solve, have outcomes that are difficult to predict, and involve considerable uncertainty (Lee, 1973; Rittel and Webber, 1973).

The practical failure of the early computer-based urban models reflected a more fundamental rejection of the 'rational planning' model that was assumed to underlie all attempts to use computers in planning. Planning methods and technologies

that were once assumed to be 'objective' and politically neutral were found inevitably to increase the power of administrators and technical experts at the expense of those who lacked the expertise to use them effectively. Information that appeared to be more accurate, credible, and objective simply because it had been generated by a computer was found to reflect politically important choices in the selection of data, the application of computational procedures, and the distribution of results (Wachs, 1982). By the decade's end, most planners had no access to – or perceived need for – the expensive, fragile, and hard-to-use mainframe computers of the era and continued to rely on manual computational techniques that had changed little since the 1950s.

Planning as Communication

Planners' faith in computing technology was reborn in the 1980s with the arrival of microcomputers which made computer-based methods and techniques readily available to planners the world over. By the century's end, planners routinely used computers for general-purpose office functions such as processing documents, monitoring budgets, and maintaining records. By 2010, planners around the world routinely used geographic information systems (GIS; to be discussed below) to process permits, maintain land-related information, and prepare thematic maps. Equally important, the increased availability of information from municipal information systems and the Internet allowed planners to quickly and easily process increasingly large quantities of spatially-related information.

Underlying these developments were new images of 'planning as communication' (Innes, 1995). Planners increasingly realized that planning involves not only the collection and distribution of numerical data and formal documents but, more importantly, face-to-face communication with colleagues and clients involving less traditional types of 'information': stories, advice, and personal experiences. As a result, planners began to recognize that the *ways* in which they transmit information are often more important than *what* they say. For example, planning forecasts could be described either as the result of highly sophisticated computer-based procedures that exclude nonexperts or as implementing easily understood models and assumptions that invite public comment.

Today's Planning Technologies

Before the advent of computers, planning data were available only in voluminous printed volumes and paper maps that were incomplete, inconsistent, and could only be updated manually. Planning analysis and communication required manually copying data from printed documents, laborious and error-prone hand computations, and preparing text, tables, maps and figures by hand.

Today all of this has changed. A wealth of spatially-related data is readily available in digital form from public and private data providers. Planners' computer-based tools allow them to analyze these data quickly and use them to produce attractive documents, charts, and maps that they can easily distribute to clients and other professionals. As a result, it is almost impossible to conceive of planning *without* computers and related information and communication technologies (ICTs). The following section briefly reviews the technologies that are most widely used by today's planners.

Geographic Information Systems

GIS are computer systems for capturing, storing, querying, analyzing, and displaying information about natural and built entities and activities that can be displayed on a map. GIS are particularly powerful analysis tools because they consider cartographic, attribute, and topological data about spatially related entities and activities. The cartographic data describe *where things are*, that is, their location relative to a reference system, and provide the information needed to prepare a map. For example, the cartographic data for the lines on a map include their location (beginning and ending points), shape (straight or curved), type (solid, dotted, or dashed), and color. Attribute data describe *what things are*, such as, their magnitude, classification, and ownership. For example, the attribute data for a tax assessor's map would contain information on the street address, use, ownership, and assessed value for land parcels. Topological data describe spatial relationships, that is, *where things are located relative to other things*. Topological relationships include: (1) adjacency, for example, the fact that France and Poland are both next to Germany but are not next to each other; and (2) containment, for example, that Paris is located in France, not Germany.

GIS have proven extremely useful for a wide range of planning applications such as analyzing and displaying spatially related information, maintaining land-based inventories, and administering permitting processes. Unfortunately today's GIS only consider the present and past and cannot support planners' particular concerns with projecting future conditions, evaluating the long-term implications of alternative public choices, and considering public policy goals, benefits, and costs.

Planning Support Systems

In response to the limitations of the current generation of GIS, the last decade has witnessed a rebirth in the development of planning models that use the tremendous analysis and display power of GIS and the increased availability of spatially-related data to develop customized planning support systems (PSS) that meet the needs of planners (see, e.g., Brail and Klosterman, 2001; Brail, 2008). The following approaches have dominated efforts in this area: (1) large-scale urban models, (2) cellular automata (CA) models, (3) agent-based models, and (4) rule-based models. (Other modeling approaches are reviewed in Trianstakonstantis and Mountrakis (2012)).

Large-Scale Urban Models

Large-scale urban models for studying the interaction between land uses and spatial interaction first attracted planners' attention to computer-based models in the 1960s (see, e.g., Harris, 1965). These models project future land uses, housing and employment for zones within a metropolitan area, and the travel by transportation mode between these zones (Miller et al., 1999; Hunt, 2005). More sophisticated models attempt to represent the complex interactions between land uses and

transportation demand, the market for land and space, and the location of households and firms over time and space. Models of this type that have been widely implemented in practice include DRAM/EMPAL (Putman, 1983), MEPLAN (Bertuglia et al., 1990), TRANUS (de la Barra, 2001), and UrbanSim (Waddell, 2002).

CA Models

CA models of urban growth have received a tremendous amount of academic attention in recent years (Trianstakonstantis and Mountrakis, 2012). CA models represent an urban area with a lattice of cells, each of which exists in one of a finite set of states; for example, 'developed' and 'undeveloped. The progression of time is modeled as a series of discrete steps with future patterns determined by transition rules that specify the behavior of cells over time (e.g., whether a cell switches from undeveloped to developed), as a function of conditions at each cell and its neighboring cells at each time step. A widely used CA model, SLEUTH, which stands for the input requirements of the models – slope, land cover, exclusion, urbanization, transportation, and hill shade – uses information on land uses at two points of time to calibrate a statistical model that projects future land use changes (Clarke, 2008).

Agent-Based Models

As their name suggests, agent-based systems attempt to model the behavior of complex systems by representing the behavior of the various agents that make up the system. Thus, for example, an agent-based urban model would represent the actions of a region's households, firms, and land developers who interact to buy and sell land via a simulated market. The behavior of each of these agents is modeled, along with their interactions with other agents and with the environment, which together determine future urban development patterns (Heppenstall et al., 2012).

Rule-Based Models

Rule-based models first became popular in planning with the publication of John Landis's landmark California Urban Futures (CUF) model, the first GIS-based urban development model (Landis, 1994). CUF and other rule-based models do not attempt to duplicate the complex spatial interaction and market clearing processes that underlie the large-scale urban models. Instead, they incorporate explicit decision rules that allow model users to specify how the model will behave. Thus, for example, rule-based urban growth models such as CUF and What if? (Klosterman, 1999) incorporate user-specified rules for determining the relative suitability of different locations, projecting future land use demands, and allocating projected land use demands to suitable sites. Similarly, rule-based impact assessment models such as CommunityViz (Walker and Daniels, 2011) and INDEX (Allen, 2008) specify rules that determine the impacts that proposed actions will have on future development patterns, public infrastructure, and the like.

The Internet

The Internet and the World Wide Web (or 'Web') provide a 'network of networks' that connect millions of computer users around the world into a seamless web of electronic communication and information dissemination. The Internet has been extremely useful in providing planners and the public with anytime, anyplace access to large databases such as the entire contents of the national census and interactive audio and video displays. It also allows plans and proposals to be distributed quickly and easily, allowing people with different skills and viewpoints to participate in the public policy-making process, independent of time and place. The recent development of powerful Web services promises to make a new generation of online models and methods readily available to planners around the world.

Today's Planning Methods

Continued advances in the power and capabilities of modern GIS and the availability of high-quality spatial data have stimulated a revolution in the area of spatial analysis. Important issues such as spatial autocorrelation and the modifiable area problem which had been largely ignored in the past are now being addressed thoroughly, and exciting new tools and techniques for analyzing and describing spatially related phenomena are being developed and refined (Fotheringham and Rogerson, 2009). Unfortunately, these developments have had little impact on planning practice and education. A host of planning methods texts were published in the 1970s, but only two (Klosterman, 1990; Wang and Hofe, 2007) have been published since then. A new textbook demonstrating how current GIS technology and traditional planning can be used to address the realities of today's planning is being prepared.

The Future of Planning Methods and Technologies

Planning methods and technologies have changed dramatically over the last 50 years, due largely to the incredible advances in ICT that have occurred since the birth of computer-aided planning in the 1960s. Fragile and expensive room-sized computers and paper 'punch cards' have been replaced by low cost and more powerful machines that fit into our hands. Today's GIS provide tools for high-quality cartography, three-dimensional visualization, and spatial analysis that could not be imagined a generation ago. A wealth of spatially related data is currently available from government and commercial data sources, increasingly via the Web. Free and easy-to-use online mapping and route-finding tools have made spatially referenced information and services a routine part of people's lives. The rapid development of more powerful Web services promises to make digital data and advanced computing tools readily available to planners around the world. Perhaps most importantly, the grand challenges of climate change, resource depletion, and environmental degradation increasingly require computer-based analysis, forecasting, and evaluation. Together these trends are encouraging academic institutions, innovative government agencies, and entrepreneurial organizations around the world to develop and apply a new generation of Web-based models and methods.

Nevertheless, experience has demonstrated that progress in the field of computer-aided planning will not be quick or easy.

A vast body of academic literature on computer-aided models and methods has accumulated since computers entered planning in the 1960s (see e.g., Harris, 1985; Klosterman, 1992; Trianstakonstantis and Mountrakis, 2012). Complex and expensive integrated land use/transportation models are used increasingly in practice, but only by well-funded academic institutions and regional transportation planning agencies. An overwhelming array of GIS-based PSS models is being developed around the world but most of them are academic prototypes or 'one off' professional applications that have not been adopted elsewhere. A number of commercial off-the-shelf PSS have been developed but these systems have been adopted only by a small number of agencies and are rarely used on a routine basis.

Important obstacles can be identified that have limited the adoption of computer-based planning models and methods (Vonk et al., 2005; Vonk and Geertman, 2008). Academic institutions are excellent venues for developing models but cannot provide the long-term support required for their continued use in professional practice. Efforts by commercial firms to develop planning models are hindered by a vicious circle: practitioners are understandably reluctant to adopt an immature and poorly known technology; the limited market for planning models restrains the ability of developers to improve and market their tools; this completes the circle by limiting planners' awareness of, and willingness to adopt, computer-based models and methods.

More fundamentally, the adoption of computer models and methods is limited by the somewhat paradoxical fact that today's planners often do little planning. Planners are so occupied by routine administrative tasks such as processing permits, enforcing building codes, and administering regulations that they all too often fail to help the communities they serve engage an uncertain and politically contentious future. As a result, the current effort to develop GIS-based planning models is part of a larger effort to return the planning profession to its traditional concern with using information and analysis to help the public more effectively engage its collective future (Isserman, 1985; Myers, 2001; Hopkins and Zapata, 2007).

The current effort to apply advanced ICTs to planning is also part of a fundamental change in our image of planning and the role that technology can play in planning research and practice. The first generation of computer models and methods was assumed to provide the foundations for value-neutral 'planning for the public' that would allow planners, as technical experts on the city, to understand the urban development process, accurately forecast the future, and identify the best policy option, with little need to involve the public. Today's planning models generally pursue new ideals of citizen-based 'planning with the public' which limit planners' role to structuring and informing a citizen-led decision process and attempt to involve stakeholders and private citizens in all stages of the planning process – understanding the past and present, identifying problems, evaluating alternative solutions, and attempting to make decisions they can support (Innes, 1996). ICT can play an important role in this effort but it will require the development of new models and methods that allow nonexperts to understand present and past conditions, clearly identify alternative public policy options, and easily evaluate their implications.

We live in an era of exciting technical possibilities, an increased appreciation for spatially referenced information, widespread concern with issues such as climate change and resource scarcity, and a growing demand for more meaningful public participation. These demands will only increase with the growing interdependence, complexity and uncertainty of a rapidly urbanizing world. Dramatic advances in ICTs may provide the technological foundations a rejuvenated profession that will once again claim its traditional role as a source of inspiration about what the future might – and should – be and promote more meaningful citizen involvement. Only time and professional practice will tell whether this potential is achieved.

Urban Policies in Asia

Mee Kam Ng, The Chinese University of Hong Kong, Shatin, Hong Kong, China

Abstract

Asia is a colorful mix of countries with varying degree of urbanization and can roughly be classified geographically into East, Southeast, and South Asia. While the state is central to the formulation of urban policies in Asia, the more developed parts put more emphasis on the green agenda, whereas the less developed parts continue to be snared by the brown agenda. Asian countries are keen to join the globalized worlds but various shades of civil societies have also challenged the impacts of the trend of globalization on local development as well as environmental and social sustainability.

Diversities

By 2030, more than half of the world's urban population will be in Asia (ADB, 2011; Clark et al., 2009). Asia is not a unified whole and geographically can further be divided into East Asia, Southeast Asia, and South Asia with distinctive internal differences. East Asia consists of Japan, poor and dictatorial North Korea, wealthy and more democratic South Korea, China (with her Special Administrative Regions, Hong Kong, and Macau), Taiwan, and Mongolia. In Southeast Asia, fully urbanized Singapore leads in terms of general economic development, followed by Malaysia, Thailand, Indonesia, the Philippines, Brunei, and the poor countries in the Indo-Chinese region including Vietnam, Cambodia, Laos, and Myanmar where only one-fifth to one-third of their population is urban. South Asia is a region with diversified cultures, people, religions, and languages. It is led by India in terms of land area, population, and economic development, followed by the rivalry Muslim countries of Pakistan and Bangladesh and the small island countries of Sri Lanka and Maldives, and landlocked mountainous countries of Nepal and Bhutan. From a political economic perspective, one end of the spectrum consists of state-centered market economies at different levels of development and the other end of the spectrum is made up of transitional socialist market economies including China and the countries in former French Indo-China.

It is impossible to talk about Asian urban policies without understanding the meaning of 'urban' in the historical traditions of diversified Asia. In the bygone past, the urban realm arose as a result of agricultural surpluses and as such cities in China used to be just administrative and market centers for their rural counterparts. The evolving urban policies in Asia are undeniably outcomes of mega trends such as millennia of indigenous histories; the age of exploration, colonialism, and imperialism in the last two centuries, the Cold War and the recent renewed round of accelerated globalization; entrenched and historically evolved microsocioeconomic and political processes; and power play among different levels of states, the business sector, and the civil society. Whether developed or developing, the nature of urban challenges faced by Asian countries is formidable: how to develop a pathway that manifests their time-honored traditions (such as emphasis on the roles of state and family relationships), conserves their fragile environments and social networks, and, at the same time, allows them to 'converge' with the rapidly globalizing world dominated by Western standards and values. In terms of the actual contents of urban challenges, these countries are manifestly very different.

The more developed urban realms in East and Southeast Asia are often seen as products of progrowth developmental and bureaucratic states that have developed close and productive relationships with the private sectors (Amsden, 1992; Wade, 1990; Waley, 2012; Woo-Cummings, 1999) in economic growth. However, increasingly this economic development strategy has given ways to concerns about environmental and social sustainability. Hence, naturally their urban policy agenda revolve around economic restructuring, environmental, social, and cultural issues in face of heightened globalization. Urban development in the less developed countries is often fueled by accelerating rural–urban migration, leading to the growth of informal economies, shanty towns, environmental degradation, pollution problems, health issues, conspicuous poverty, urban crimes, and extreme social polarization.

Whether a country is highly or hardly urbanized, the urban realm is critical for its development (UN Habitat, 2011) and cities contribute over 80% of gross domestic product (GDP) in many Pacific Asian countries (ADB, 2012). The quality of urban policies is often determined by the level of decentralization, including the dedication of resources to build hard and soft infrastructure. It is because according to Clark et al. (2009, 6), "the central government controls more than 70% of the revenues." As argued by Skocpol (1982, 6), "a state's means of raising and deploying financial resources tell us more than could any other single factor about its existing capacities to create or strengthen state organizations, to employ personnel, to co-opt political support, to subsidize economic enterprises, and to fund social programs." At the local level, the mode and quality of local governance have to rely on the availability of resources (including human resource such as the quality of the bureaucracy), and the scale of urban challenges in terms of economic opportunities, urban poverty, levels of air and water pollution, solid waste production, and so on. The trajectory of actual development on the ground very often is determined by the philosophy and power held by the stakeholders involved.

While it would be impossible to review urban policies in all the countries in Asia, the following, nevertheless, attempts to highlight key urban policies adopted in individual cities in

countries within the three subregions in order to give readers a flavor of the array of urban policies in diversified Asia.

East Asia

Although Japan has not really turned around since her economic crisis in the last decade of the twentieth century, her capital city, Tokyo, has always been at the forefront of promoting environmental protection and sustainable development. The city has faced socioeconomic challenges such as declining birth rates, aging population, and keen city competition and the Tokyo Metropolitan Government formulated the "Tokyo Vision 2020: Driving change in Japan/Showing our best to the world" in 2011. The key urban policies are related to Japan's vulnerability to natural hazards, including the construction of a disaster-resilient city; the need for efficient, locally produced, consumed and independent, distributed power production; and boosting global competitiveness through development as an international hub (op cit., 2011). To produce a resilient city, priorities are given to develop earthquake-resistant, affordable, and sustainable housing and communities fit for different age groups and will last for generations (BUD, 2011, 4). The city has also promoted public–private partnership, land readjustment means, and urban design to regenerate the Capital. Flagship projects include Roppongi Hills and the 31-ha Shiodome railway yard next to Shinbashi Station. They were undertaken by the private sector within rules and regulations set by the government and their eventual developments were also shaped, to certain extent, by voices from local communities (Waley, 2007). The 10-year project for Green Tokyo and the 10-year project for a Carbon-Minus Tokyo (Tokyo Climate Change Strategy) have been formulated to realize the Tokyo Vision 2020. The New Strategic Guidelines for Greenery formulated in 2006 aims to involve the public and private sectors and the civil society in greening the city. And various plans and laws are in place to use systematic and integrated measures to recycle resources. About 1300 facilities with a total annual consumption of fuels, heating, and electricity of at least 1500 kl crude oil equivalent are required to formulate, report, assess, and announce on measures against climate change (BOE, 2009). The city also uses its cutting edge technology to launch the Tokyo Ubiquitous Technology Project such as IC tags to allow access of information by "anyone, anytime, anywhere" in the capital city.

Similar to other Asian countries, South Korea is facing an aging population situation, demanding more elderly housing, elderly friendly environment, and transportation policy (OECD, 2012: 77). South Korea could have done a better job in developing a coordinated urban development strategy and help promote the internationalization and competitiveness of Seoul and other cities (OECD, 2012) but she has continued to practice an urban containment policy. As in the case of Japan, South Korea has nurtured big business interests, chaebols, headquarters of which can be found in the capital city, Seoul. In her capital region, the city, Seoul, has suffered from high-density development, escalating property prices, traffic congestion, intensive air pollution, and intense competition with and outside Korea. Subcenters have been developed to decentralized development. Popularized by the pop song *Gangnam Style*, Gangnam, a sub-center developed through land readjustment in the 1970s has become "the most expensive residential area, the most dynamic business area, and the most active entertainment area" (Kim and Han, 2012, 147).

South Korea has also experienced a 'green turn' of their urban development strategy. The revitalization of the once concrete-covered Cheonggye stream in 2005 has become a symbol of successful city-center regeneration. In 2008, the government launched the "Green New Deal" and in 2009, "the National Strategy for Green Growth up to 2050," both aim to "mitigate climate change, create new engines for economic growth and improve quality of life" based on green technology and low-carbon production fueled by renewable energy (op cit., 2012, 88). A five-year plan is developed to specify policies, objectives, and targets, as well as resources allocation. In 2008, Korea published her *Urban Vision for 2020* aiming to nurture eight growth engines (business, information technology (IT), tourism, green industry, biomedical, design, finance, and contents), improve urban living conditions, establish urban identity, and restore the natural environment (op cit., 2012, 102). In order to build a "polycentric mega-city," planning authority is decentralized to the local level to encourage redevelopment, densification, and mixed and transit-oriented development. Given the increasing number of immigrants to cities such as Seoul, the urban policies need to be adjusted to the cultural needs and practices of these immigrants.

Development of Taiwan took off in the 1960s when the Nationalist Government pursued the Ten Great Infrastructure Projects across the island state. Today, key urban challenges include an aging population, environmental risks, economic and spatial restructuring, sustainable development, and international competition. And the goal is to develop Taipei as a forward thinking, charming, livable, cultural, eco, cybernetic, and safe city (UDD, 2005). In 2003, the Taipei City Sustainable Development Council was established to build Taipei into a sustainable world city that pursues smart growth, recycling, and progress sharing (Taipei City SD Council, 2004). Similar to Tokyo, Ubiquitous Intelligent Taipei is a major policy for the Taipei City Government, providing residents access to various kinds of services such as transport, parking, telecare, etc. (TMG, 2010). The city has been proactive to reduce carbon emission and an interdepartmental "Greenhouse Gases Reduction Promotion Team" has been formed to execute the "Energy Saving and Carbon Reduction Plan" that involves industrial and commercial energy conservation, subsidization of environmentally friendly vehicles, waste recycling and reuse, etc. (Secretariat of TCG, 2009). And the active civil society has played an instrumental role in shaping the environmental and social policies (Lyons, 2009). However, the politically isolated island state has faced keen international competition especially with the rise of Chinese cities and has in recent years adopted more neoliberal measures in marketing the city such as tax cut for the rich, relaxing rules and regulations related to the protection of labor rights, and encouraging redevelopment through the provision of plot ratio and gross floor areas bonuses.

The largest country in East Asia is Socialist China, once an underurbanized country with a *hukou* (household registration)

system that strictly controls internal migration between rural and urban areas. However, since late 1978, the giant nation started to embark on economic reforms and open door policies, leading to decentralization of administrative functions and rapid urbanization processes especially along the coastal regions, first through the development of the Special Economic Zones (SEZs), then the 14 open coastal cities, the open economic zones, free trade zones, and development zones. The transition from a centrally planned socialist economy into one with market mechanisms has significant impacts on old urban areas in the reforming cities. The heavily used compact inner city areas that carry the historic heritage and collective memories of many urbanites were increasingly seen as problematic sites that need to be 'fixed' and redeveloped into land uses with higher exchange value such as commercial and retailing uses. Furthermore, following the practice of capitalist Hong Kong, the leasing of land use rights has become an important financial resource to fuel infrastructure development. According to Article 18 of China's Administration Law on Real Estate (1994), land premium paid by developers for the right to use land was collected by the State Treasury and when this law was revised in 2004, 30% of the land revenue goes to the Ministry of Finance and 70% to the relevant local government (Choe et al., 2008, 38). And many municipal governments have used the financial resources to provide infrastructure in order to attract outside investments to propel economic growth. And no place in China has a more dramatic urban story than the legendary 'instant city,' Shenzhen SEZ north of Hong Kong.

The country's first SEZ has grown from a city of merely 0.3 million in 1980 to an informally quoted figure of 17 million today. In three decades' time, the city's GDP had grown more than 4184 times, from RMB196 million in 1979 to RMB820 billion in 2009 (Shenzhen Statistics Bureau, 2010: 30). The first master plan of SEZ was formulated in 1980 and had a planned area of only 50 km^2 and by the third master plan, the SEZ had incorporated its two neighboring rural counties as districts and the whole city was expanded to 2000 km^2 (Office of Shenzhen History, 1997). Certain slogans summarize Shenzhen's philosophy in developing her urban realm: "Time is money, efficiency is life" and "Hong Kong's efficiency, Singapore's environment." At the turn of the twenty-first century, the dramatic growth of the city has led to constraints of the carrying capacity of the natural environment, shortage of land supply, rising costs of production, and pressing need to restructuring the economy in face of keen competition within and beyond China. To cope with these challenges, the city repositions herself as "an experimental site for integrated reforms to develop a creative and 'circular' economy," to collaborate with Hong Kong to develop newly reclaimed Qianhai as "an international financial, trade and logistics centre," to serve as a base for national high-tech industries and cultural heritage and an integrated transport hub as well as an internationally renowned tourism city by the sea (Ng, 2011: 640). The city also began to pay more attention to sustainable urban development and the quality of environment. To cope with excessive land occupation, the city adopts a new land policy to divide land uses into 'no-go' areas (44%), 'restricted development' areas within the 'ecological control line' (5.8%), 'developed' areas (32.5%), and 'suitable development' areas (17.7%).

The Shenzhen SEZ was built north to Hong Kong, a British colony between 1842 and 1997. Hong Kong's return to Chinese rule coincided with the outbreak of the Asian financial crisis and the city plummeted into a prolonged economic depression that threatened the tacit social contract between the growth-oriented government and the once politically apathetic civil society. Hong Kongers, especially the younger generation, have become much more vocal after 1997 and have seized every opportunity to exert their right to participate in deciding on the planning and development of the city. As a self-crowned 'Asia's World City,' the nondemocratic administrative Special Administrative Region government has to maintain the city's competitiveness amidst the dramatic growth of aspiring 'world cities' in China and beyond while also addressing domestic issues. Key challenges in the urban realm include escalating property prices, air pollution, solid waste management, undesirable urban living environment, as well as social conflicts arising from the intensified integration between Hong Kong and the China mainland. The current government has stepped up measures to search for more housing sites to check the mounting property prices. Following China's carbon intensity reduction target, the government has also published the city's *Climate Change Strategy and Action Agenda* in 2011. The city's latest Urban Renewal Strategy 2012 was reformulated to encourage community-initiated redevelopment efforts, that is, owners of buildings in poor conditions within identified redevelopment sites could seek the service of the Urban Renewal Authority to facilitate their redevelopment efforts. Environmental policies have also been developed to improve air quality, minimize waste, and promote recycling. New building regulations have been developed to ensure more sustainable urban form. Hong Kongers have been very proud of their core values including rule of law, anticorruption institutions, and privileging markets over government intervention. The government has to be extremely vigilant in responding to the community's concerns over the erosion of the city's core value as a result of inevitable and intensifying integration with the mainland at all levels.

Southeast Asia

Multicultural Singapore has been known for its urban affordable housing, transit-oriented transport policies, and heritage conservation efforts. In recent years, its "Active, Beautiful and Clean" (ABC) Waters program can be seen as one of the most creative and sustainable urban development policies in face of climate change and global warming. Active waters aims at providing new community spaces and bringing people to water for recreational purposes, Beautiful waters refers to integrating aesthetically reservoirs and waterways with neighborhood parks and landscape, and Clean waters concerns enhancing water quality through holistic management of the city's surface runoff through natural cleansing elements (National Waters Agency, 2011). The ABC Water Master Plan includes 100 project sites and efforts have been made to promote the ABC Waters Design concepts such as green building design elements (Building and Construction Authority's Green Mark Scheme has been in place since 2005), artificial water bodies creation, and flood control of storm water runoff at source into the

projects undertaken by public agencies and the private sector (op cit., 2011: 4). The Prefabricated Extensive Green Roof Tray system is also developed to provide cost-effective 'instant' green roofs (BRI, 2011). Indeed, all Singaporeans are served by modern sanitation and the government manages the water loop in an integrated manner, with two-thirds of the city functioning as local catchment areas collecting and storing rainwater. And a 3P (people, public, private) Partnership Approach to engage the community to take ownership of the water bodies or to encourage the private sector and grassroots organizations to organize or participate in activities launched at the ABC water sites (op cit., 2011: 6). Unlike her more developed Asian neighbors, a vocal and resistant civil society is absent. Nevertheless, the planning authority has encouraged public participation and the formation of focus groups to solicit information, the typical state-centered Singaporean style.

Another rapidly growing Southeast Asian country is Malaysia. Like Singapore, Malaysia is a multicultural and multiracial society, although its 'bumiputras' ('sons of the soil') policy favors the Malays over the Chinese and Indians and has indeed been increasingly challenged. Under the leadership of the then Prime Minister Mahathir bin Mohamad, Malaysia's economy has moved toward high technology-based industries. To facilitate this restructuring process, the Multimedia Super Corridor project between Kuala Lumpur City Centre and the International Airport with the Cyberjaya intelligent city, the country's 'Silicon Valley', at its center was constructed. Within the self-contained Cyberjaya are central flagship enterprise, commercial and residential zones with ecofriendly and low-density developments that aim to preserve nature and maintain an excellent quality of life (Yuen et al., 2006: 238). The target is to locate 500 IT companies in the city by 2020 (op cit., 2006: 240). And this initiative demands interrelated changes in the urban realm: providing urban services that are on a par with international standards, redesigning curriculum and education system, and issues of urban poverty as high-tech industries typically employ fewer workers.

The capital city of Thailand, Bangkok, has suffered from traffic congestion, air pollution, water pollution with untreated wastewater discharged into the public sewers, land subsidence, and growth of slums. The city develops the Metropolitan Master Catalogue for 50 districts to guide physical development through the formulation of a plan based on local strategic agenda, regulations, and database (Cities Alliance, 2005: 58). Through the Bangkok Comprehensive Plan, air pollution is tackled through the development of mass transit, establishment of vehicular emissions standards, promotion of nonmotorized transport, and the use of alternative fuels (op cit., 2006: 59), as well as mobilizing volunteers to spot 'black smoke vehicles' and to 'protect (monitor) air quality' in factories and construction sites. To arrest land subsidence and damage to infrastructure, policies and regulations on groundwater extraction have been developed to control effluent standards and wastewater treatment plants to protect water quality (op cit., 2006: 59). Community and volunteer efforts have also been mobilized to identify solutions to garbage dumping, wastewater discharge, and to develop environmental projects.

Indonesia experienced a dramatic decentralization push in the late 1990s, a result of the Asian financial crisis and the widespread demands from the civil society. With the implementation of Law 25/99 (Fiscal Balance between Central and Local Governments), except national defense and security and foreign affairs that remain under the purview of the central government, local governments are responsible for the judicial system, fiscal and monetary matters, and macroeconomic planning. Various functions, financial resources, as well as 2.3 million staff from 4000 government departments and 20 000 public facilities were transferred to local governments within 1 year (Turner et al., 2003). At the same time, democratization was initiated allowing for the direct election of national, provincial, and district governments and both trends have led to the need in revising various rules and regulations and a renewed understanding of the roles of the private sector in the development process (Sarosa, 2006). Despite the good will of the central government in decentralization, the transferred responsibilities have become challenges to the local governments that are often short of administrative skills and revenue sources. Inspired by Singapore, the mayor of Tarakan, a city in East Kalimantan, devised 'three pillars' of development: human resource development, rule of law, and provision of people's welfare as economic development (op cit, 2006: 174). The mayor mobilized the community to manage and conserve the environment and turned down an investment to exploit coal in the city (op cit., 2006: 174). In the capital city Jakarta, high urbanization has resulted in traffic jam, flooding issues, waste management, health services, and education and employment opportunities, especially for the poor. To tackle the key issues, the municipal government has endeavored to adopt the transit-oriented development concept and develop mass transit while reducing the road ratio to 10%. It has also adopted an integrated flood control system to restore the riverside environment, enhancing the drainage systems and optimizing the functions of urban rivers.

China's reawakening has stirred other transitional economies in Asia such as Vietnam and *doi moi* (renovation) was initiated in 1986. And *doi moi* has unleashed economic reforms, urban planning efforts, urbanization, and calls for decentralization. Similar to other early urbanized countries, providing infrastructure to sustain economic growth and a basic quality of life in the urban realm has been a key challenge, especially when the central government continues to control the budget and there is a general lack of land use planning and development enforcement capacity. A high percentage of motor cycles (4 million in Hanoi alone) contributes to heavy traffic congestion, and haphazard urban and industrial developments present pollution problems and difficulties in rationalizing land uses. Not all urban areas are connected with sewage, and water and electricity supply is also an issue. The lack of relevant human resources to tackle these issues through policies, legal means, and administrative measures in a holistic manner has worsened the situation. As a result, foreign official development assistance has been instrumental in building the country's institutional capacity in the urban realm. For instance, the project of Nhieu Loc-Thi basin canal of Ho Chi Minh City, funded by the World Bank and Ho Chi Minh People's Committee, involving the separation of sewage and storm water drainage, lessen the threat of flooding, promoting economic growth and enhancing public management of

private entities. Through extensive public engagement, the project not only helps improve the quality of life, but also has boosted the local capacity to plan, construct, and manage this type of urban projects (Lang, 2006).

South Asia

In South Asia, the key challenge is related to the mode of governance and the lack of resources at the municipal level to provide, operate, and maintain various urban services. The central government plays an important role in South Asian countries. In India, the central government decentralized more powers to urban and rural local government bodies through the 73rd and 74th constitutional amendments in 1992 (Choe et al., 2008: 4). The 28 state governments are responsible for urban development, management, and service delivery but the central government initiates policies and programs of national importance such as poverty reduction, housing for low-income urban households, and infrastructure. State governments reserve the rights to allocate responsibilities and functions to local governments through tax sharing or expenditure transfer (Mathur, 2006: 137). In 2005, the Indian government launched the Jawaharlal Nehru National Urban Renewal Mission in 63 cities to improve and expand the economic and social infrastructure of cities, to ensure access to basic services including housing and land for the urban poor, to initiate wide-ranging urban sector reforms, and to strengthen municipal government functions (Choe et al., 2008: 6). In the capital city, the Delhi Municipal Corporation started the Bhagidari initiative in 2000 to ensure that utilities providers cater to the needs of the residents through interactive meetings with citizens' groups such as welfare associations, private sectors, industrial organizations, and school welfare committees. While the central and state governments provide grants and finance to aid infrastructure development at the local level, the key challenge, nevertheless, is to boost financial capacity of local municipal governments to maintain service delivery functions such as encouraging public–private partnership, sale of land use rights, and application of cost-recovery principle to construct urban infrastructure (Choe et al., 2008: 141).

A case in point is the Ahmedabad Municipal Corporation (AMC), established in 1950 under the Bombay Provincial Municipal Corporation Act, 1949. Key functions of AMC are to provide water and urban amenities and to run hospitals, medical colleges, and local transport; its main sources of revenue are taxes on properties and goods that enter the city. To improve the collection of the property tax, the AMC disconnected water supply and drainage lines and other 'name and shame' measures on nonpayment of property tax, and a valuation manual and database are developed to allow professionals to check and collect taxes on goods that enter the city (op cit., 2008: 145). AMC even pioneered in the issuing of municipal bonds to raise the necessary funds for financing the much needed infrastructure. Increased cash flow has helped improve the delivery of services, which in turn restores a more trusting relationship between the government and citizens. Securing financial resources enables the city to launch environmental improvement and sustainable transport initiatives. Ahmedabad has the 'only successful running Bus Rapid Transit' in India but research shows that the urban poor do not use formal public transport. In fact, 72% of women and 51% of men in the low-income households 'traveled less than 3 km' and rely on nonmotorized transport, with 60% poor women walking to work (Mahadevia et al., 2012: 3–4). Making public transport affordable is an urban challenge in these situations.

Bangladesh is a secular democracy but her mode of urban governance has a lot to be desired because of inadequate decentralization, a general lack of local political leadership, and numerous interrelated urban problems such as weak economic growth, social polarization, insufficient utilities, transport, education, health and leisure facilities, slums and squatters and the accompanying social distress in law and order, or the conservation of heritage and culture (Islam, 2006: 54–55). The City Corporation Ordinance or the Pourashava Ordinance constrains the power of local city corporations, rendering them little authority to mobilize resources or develop programs of commercial interest (op cit., 2006: 58). Hence, international organizations have been instrumental in building her capacity in urban governance. For instance, the United Nations Development Programme and the UN-Habitat had assisted in the country's urban policy formulation and drafting of master plans for cities. The World Bank has supported water supply and sewage treatment and transport projects in Dhaka and the Asian Development Bank has provided assistance in service deliveries as well as enhancing urban governance. In the country's second largest city, Chittagong, besides her Nobel laureate Professor Muhammad Yunus who first developed the concepts of microcredit and microfinance and later developed the Grameen Bank, the city corporation has been instrumental in establishing sustainable social, economic, and environmental projects. With the able leadership of the then three consecutive time mayor Chowdhury, the city developed self-sustaining programs on infrastructure development, garbage disposal, parks and playgrounds maintenance, water supply to poor neighborhoods, power plant installation, solid waste recycling plant, shopping malls, hospitals and health care centers, and various education facilities from kindergartens to colleges (op cit., 2006: 58–60). Mayor Chowdhury's downfall in 2007 as Bangladesh changed to an army-backed government highlighted the problem of the country's centralized mode of governance. It also highlights the challenge of political stabilities in the developing countries.

Conclusion

Perhaps one defining characteristic of the urban realm in Asia is the important role of the state, especially the central government, and it was coined as "the developmental state" (Wade, 1990; Woo-Cummings, 1999). Urban development at the local level is dependent on the degree of decentralization set by the central government. Deployment of fiscal and human resources by growth-oriented states to develop and tailor-made appropriate and integrated policies is undoubtedly the key to success in the developed cities. Traditionally, the Asian states and the private sectors have developed strong relationships such as the roles of zaibatsu in Japan, chaebols in Korea, the state-led market system in Singapore, not to mention the unique socialist market economic system

in transitional China. The strong relationships between the state and the private sector have produced unique political economies over time, which are different from a typical free market economy that emphasizes on the existence of a level-playing field for all economic actors. However, accelerated globalization and the need for more foreign investments have led to the launching of 'neoliberal' economic policies. Yet, one may argue that the nature of Asian 'neoliberalism' is different from her Western counterpart. Instead of rolling back the state welfare system and rolling out market-driven reforms, Asian 'neoliberalism' is more about 'weakening' certain state–private sector relationships in order to nurture the growth of a more inclusive market.

Obviously, developed or developing, the green and the brown agenda continue to be relevant as these cities struggle to address domestic issues including social polarization, poverty, and degrading environment and at the same time, the need to compete for overseas investment and international trading links and status. The green urban policies are often launched to boost global competitiveness and these include measures to ensure disaster resilience, development of renewable energy, ICT infrastructure, and green urbanism to counteract climate change and global warming. For the developing Asian countries, urban policies are related to enhancing the capacity of local governments to tackle pollution issues and to provide adequate infrastructure to satisfy basic needs. Indeed, evolving social contexts have complicated the launching of these various policies. Domestic and international migrants into cities have created challenges to the local governments. While these migrants usually make great contributions to urban development, accommodating their multifaceted needs and harmonizing their relationships with the local communities and building a truly multicultural society could be daunting tasks. The developing and maturing civil societies in Asia are slowly (re)shaping the various urban policies, challenging the state–private sector nexus in the more developed countries, and substituting inefficient government or weak private sector to satisfy their socioeconomic needs in the less developed ones. The Asian urban drama will most likely continue to grip the world's attention as the twenty-first Pacific Century unfolds.

Urban Policy in Europe

Patrick Le Galès, Sciences Po, CNRS, Centre d'études européennes, Paris, France.

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article argues that urban policies have a long inheritance in Europe as they were invented in medieval trade cities all over the continent. The long-term territorialization of European societies and the importance of the state explain why urban policy is particularly concerned with places in Europe. But urban policy are not only explained by urban factors, they are one type of public policies among others hence the emphasis on public policy analysis and capitalism to understand the transformation of urban policy.

Urban policies are public policies and Europe is the land of public policy. Historically, urban policies in Europe started with the institutionalization of power in Greek cities and the Roman Empire. Taxes were raised; some specialized experts and administration emerged; ideas were put forward; protection, control, and war were at stake; securing food supply or water was central; and elites invested resources to build, plan, develop cities, and control their population. In Europe, urban policies developed with the coming age of the medieval communes organizing those flourishing cities which, along the Baltic and the North Sea on the one hand (St Petersburg, Hamburg, or Amsterdam, for instance), the Méditerranée on the other hand (i.e., Venice, Florence, or Barcelona), and those in between (Bruge, Cologne, Prague, or Lyon), became the center of the first capitalism, that of merchants and traders. Within those fast developing cities, new ways to govern and to implement urban policies emerged: statistics, bureaucracies, planning, public private partnership to develop new neighborhoods, and forms of policing. Then, the conquest, organization, and control of space became a classic task states develop in the process of state making and state institutionalization.

Like any public policy, urban policies are always historically and geographically located in a given society and at the same time influenced or structured by large-scale processes or paradigms. Politics is part of urban policies, hence the importance of power relations, forms of capitalism, and state. Contradictions are essential to understand urban policy: not only the contradictions of the capitalist order where public policies aimed at dealing with uneven developments and inequalities while supporting capitalist accumulation and competition between cities but also the contradictions between organizations, laws, and agencies. Urban policy must be understood as a policy with the classic question raised by Harold Laswell in the US in 1936: *Who gets what, when, and how*? An urban policy is always an attempt to change existing situations, a set of power relations more or less institutionalized, and is also an experiment as suggested by Dewey (1927) and the pragmatists, hence the political dimension. However, by contrast to the pragmatist urban scholars have emphasized on structural political dimensions: conflict, political order, class, coercion, resistance, and power relations. As any public policy, an urban policy combines: (1) some principles, ideas, representations, values, and goals to be achieved; (2) actors, individual or collective with unequal resources (money, expertise, legitimacy, and networks), more or less organized in different ways; (3) institutions, budgets, rules, and instruments; and (4) results. Urban policies are in part inherited, but can also be constructed and the label may reveal strategic actors' activities rather than substance. Implementation is central. Urban scholars too often consider urban policies as specific: they fall into the sector centered trap as do environment, social policy, gender, or economic policy specialists. Urban policies, including planning, are public policies which are for the most part similar to the rest of public policies.

Analyzing urban policy is fraught with difficulties for different reasons: Firstly, defining the urban is no small problem. Long gone are the days when a city was surrounded by walls with different social structures and rights for citizen. Beyond classic definition of cities in terms of concentration of people, buildings, exchanges, and land, i.e., forms of density of individuals, networks, or the built environment, many now see a gigantic urban world where no one nowhere is immune from the urban, a global urban world, i.e., a planetary uneven urbanization (Brenner, 2013: p. 109). If the urban is everywhere, it is nowhere and cities then do not matter in that perspective. The question of boundaries is never solved. It follows that critical geographers may analyze urban policy as either irrelevant, or in constant flux, as an unstable assemblage of mobile policies. This has proved useful to mock fads in urban policy such as the 'creative city' discourse promoted by policy entrepreneur, selling his 'best practices' to cities all over the globe and in Europe alike (McCann and Ward, 2011). But neither urban policies nor cities are so fluid and the assemblage metaphor is often not so relevant for urban policies.

Alternatively, urban policy is explained by the transformation and the requirements of capitalism. Here the argument can be developed in more or less functionalist way. Neoliberalism as a global paradigm has been used in all sorts of more or less rigorous ways to explain urban policy change (Brenner, 2013). Others focus on urbanization processes and convergence. If there is a general theory of urbanization, for instance a Marxist-inspired theory (Harvey, 1985; Brenner, 2004 among others), urban policy is understood as either the attempt by the state to accompany or limit the problems associated with the urbanization process, or, as Brenner put it urban policy is defined as "encompassing all state activities orienting towards the regulation of capitalist accumulation" (p. 2). Urban policy in London, Helsinki, or Prague may be

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74058-X

seen as an attempt to deal with the spatial contradictions of capitalism.

There is another problem linked to the definition of the urban: while it was classically understood in relation to fixity, as a place in space, a booming research current has shown the importance of physical and virtual networks, circulations, and links. Milan is Milan but is also structured by Senegalese neighborhoods of Dakar through regular in and out migration, to London and New York through financial circulations, and so on. Images, ideas, representations of cities travel, and the virtual cities of science fiction writers, movies, or games are also part of the urban world.

The tension between state and cities is a powerful reminder of the dynamics of rescaling. The scale question was brought back on the agenda by critical geographers, most notably Neil Brenner (2004), and political scientists (Keating, 2013); so, for instance, in urban policy terms, one cannot just describe policy initiatives developed by central governments. Urban policies are initiated and implemented at different levels closely articulated, enmeshed, or in competition, and with many contradictions: neighborhoods, cities, metropolitan governments, regional or federal public authorities, the state, the EU or influenced by international organizations (Le Galès, 2002). This does not occur at random; there is a politics of rescaling where interest groups mobilize to locate resources and policies. Local welfare policies are a typical example of this general dynamic (Kazepov, 2010).

Urban Policy: How Does Europe Matter?

Urban policy in Europe makes sense in relation to some particular features of Europe. Firstly, European societies are deeply territorialized, cities have a long history, and Europeans have low rate of transnational mobility.

Urban policies in Europe mainly deal with places: European societies are deeply territorialized, levels of transnational mobility are lower than in other parts of the world and only increase slowly. With the exception of Britain, many urban Europeans have dense social networks in cities and when they move, they often come back where they were before, in particular in the south (Andreotti et al., 2013). By contrast, American urban policies, for instance, make sense if one remembers the origins of colonial towns, the industrial development of the North East, the Western Frontier, the race issue, the federal system, and a particular understanding of freedom which makes public policy often illegitimate and by contrast, mobility a pillar of individual freedom (Imbroscio, 2012). But if Americans are born to run, Europeans are rather born to stay, or to move slowly.

Historically, Europe has been created and shaped by cities (Pinol, 2012; Le Galès and Therborn, 2010), and the long history of urban Europe made of medium-sized regional capitals has been well accounted for (Hohenberg and Lees, 1985). Urban Europe came into full development during medieval times, thanks to the development of the first capitalism of trade but in relations to existing settlements inherited from the Catholic Church or the Roman Empire. Cities gave rise to modern Europe and states came of age in relation to them. The European urban structure has been relatively stable ever since, with two important caveats: the institutionalization of the modern state (the making of national and/or imperial capital and the role of various wars), and the massive disruption of the industrial revolution in Britain, in particular, and also in Belgium, Eastern France, Germany, and Scandinavia.

European societies are deeply territorialized societies because of the tradition of stable peasants on their land and the long history of medium-size cities (Kaelble, 1984; Bagnasco and Le Galès, 2000). Britain, where industrialization shaped the urban structure more than anywhere else, is an exception. The political order of modern Europe is the result of the interaction between this longer standing structure of cities and the latter emerging as nation-state territorial units (Tilly, 1990). In due course, 'voracious states' consolidated with or against 'obstructing cities' (Tilly and Blockmans, 1994). The making of the modern state and the coming age of the second (industrial capitalism) marked the end of the golden age and autonomy of occidental cities. Urban policies gained prominence in those medieval prosperous cities, which were the centers of trade. The importance of the urban government was stressed as the city developed upon the movement of medieval 'communalization' (i.e., communes being formed through acquiring a *charter*). Cities became institutionalized associations, autonomous and autocephalous, active territorial corporations characterized by autonomy and capacity for action toward the outside (the lord, the prince, the abbey, the bishop, the state, the emperor, and rival cities), and led by urban officials. Medieval urban governments, controlled by the urban bourgeoisie, developed democratic institutions, and commerce left their mark through the edification of monuments symbolizing their power: squares, town halls, beffrois, or campanile. They invested resources in city centers. Urban policy all over Europe first inherits a conception of power, the centralization of public buildings, an understanding of politics (including protest), a rather encompassing view of the city as a political beast with long-term legitimacy resources associated to the elected representative, for instance, the mayor in some countries.

The long history of state making is replete with stories of national elites allying or fighting those burghers and their administrators. From the early seventeenth century, as Foucault explained (2007), the modern idea of police and government emerged. Urban policies were conceived in relation to the ministries of police and the framing of society by state dispositifs (Miller and Rose, 2008; Dean, 2010). The rise of nations and modern states, more or less operational in Western Europe by 1870, paved the way for powerful processes of nationalization of European societies and differentiation among them through urbanization, politics, culture, labor market mobility, industrialization, production, consumption, the making of a more class-structured society, wars, and the one hundred years development of public policies: infrastructure, education, welfare state, labor market, or urban policy. In industrial cities, for instance, in the UK and also in Germany, France, and Scandinavia, the scope of social problems led elites in urban government to pioneer policy programmes in housing, planning, basic elements of welfare, and education (De Swaan, 1988), and hygienist concerns led to the 'haussmanization' movement of city rebuilding together with the emergence of local public goods or to the rise of modern planning. Urban governments played a key role in providing

basic utilities and services such as water, sewage, street lighting, later gas and electricity, firemen and transport, not to mention slaughterhouse. This development was diverse, fragmented, contested between a conservative petty bourgeoisie and the municipal socialism movement, and more consistent in the North of Europe than in the South. Most local government in Europe gained legal recognition in the second part of the nineteenth century. Gradually, a professional local bureaucracy emerged to deal with those developments.

Later, in most of the post-1945 period, within the social democratic compromise of most European states, the role of urban government was structured by center–periphery relations (Goldsmith and Page, 1987, 2010), i.e., in national terms and as part of local government. Urban governments differed in Europe because each country had a different constitutional setting, different rules, different public finances systems, different political systems and traditions, different organizations to provide services, and different police forces. Urban policy was mostly understood in terms of infrastructure provision. European cities have been structured by large amount of public expenditure, translated in terms of welfare services, education, buildings, roads, housing, etc. Urban policy was in many ways part of the larger development of the welfare state and the modernization for industrialization. Urban policy was on the other hand related to modernist planning promoted by rational heroic planners against narrow local interests from the path. The reconstruction of cities after the war in Cologne, Dresden, Coventry, or Le Havre gave ample evidence of this modernist urban policies, accentuated in the case of Eastern Europe under the socialist regimes as evidenced in Bucarest or Varsaw.

Urban Policy: Inheritance, Institutionalization

Urban policies are for a large part inherited and sometimes, the result of ad hoc combination. This is central in the European case because of the long standing of the autonomous cities and municipal government on the one hand and the particular strength of states and public policies on the other, including in postsocialist cities (Stanilov, 2007). Urban policies deal with the inheritance from the past (city centers, infrastructure, renovation of working class/immigrants estates) with a mix of social, cultural, economic, and policies to redevelop the material side of the cities, buildings, housings, and utilities. Inheritance means institutions, finances, banks, professions, ministerial bureaux, urban forms, material environments, agencies, ways of doing things, knowledge, budgetary rules, clienteles, professional experts, and interest groups. Urban policy in Europe is strongly institutionalized with rules, budgets, interest groups, policy instruments, and political organizations rooted in the urban policy sector. Problems emerging on the political agenda are in part the result of this past: renovating and protecting old city centers (policy for centro storico in Italy), modernizing centers with strong local bourgeoisies, i.e., the major issue in European cities of heritage maintenance, or dealing with the long-term decline of industrial cities or neighborhoods (a few shrinking cities in oriental Europe or Northern England like Sheffield, the suburban large social estates in Britain, France, or in Roma), or renovating the utility infrastructure.

There is a huge literature about urban policies. Unfortunately, as often in the policy world, a good deal is written about specific initiatives, the 'new'policy of the day analyzed in urban policy institutes. A lot of 'new initiatives,' specific program, and much heralded 'urban new project' are no more than the recombination of those different elements, describing government initiatives, sometimes evaluating them under limited parameters. A classic New Public Management recipe consists for political leaders in announcing new policy initiatives all the time in order to create movement, pressure for change, complete lack of transparency, and incapacity to evaluate the impact, i.e., another way to play the blame game (Hood, 2011). At worse, the influence of public choice models lead to rankings, the search for best practice, and normative best recipes which make sense for neoclassic economists but not for social scientists, assuming there is more to policy goals than optimizing economic development.

In most cases, not always, urban policies in Europe nowadays are in part a continuation of what was done before and is deeply institutionalized from one country to the next and from one city to the next, i.e., investment in key infrastructures, transport and utilities (could be privatized in particular in the UK), renovation of the city center including a strong cultural drive and marketing, forms of planning, recreation of public spaces, high profile urban projects and buildings, policing (controlling marginal groups, the poor) and maintaining public order, social policy, economic policy to promote innovation and support to firms and finally policies to renovate neighborhoods in crisis, mostly in outer cities estates but sometimes in the center (Brussels), with a mix of integrated policies and some sort of integrated approach for specific places.

Urban policies do not change all the time in relation to any new idea in the wind but the implementation process shows strong uncertainty and diversity (Crosta, 2009). And the ideas are also relatively stable. Stockholm, Helsinki, or Copenhagen are characterized by long-term economic, cultural, and social urban strategies developed in tension between state and urban elites. Urban policies in London are still characterized by the need to develop the British capital, to account and deal with the interest of the City of London, to develop infrastructure, and to renovate the eastern part of London, including the former docks. By contrast, there are reasons and a particular set of social and political relations to explain why urban policy in Napoli or Marseille has achieved little over the past 30 years. There are increasingly international powerful economic interests playing a role in urban policy, but powerful interest groups within cities, including voters, should not be underestimated either.

Historically, three countries had clearly defined or labeled urban policy: the Netherlands, where cities created the state, Britain, and France. In the 1980s and 1990s, not without connection with the making of European networks supported by the EU, those national policies became more mixed, disseminated all over Europe and became more similar, encompassing all these different dimensions. Kazepov's important edited volume on cities in Europe (2005) clearly

provides examples of the characteristics of urban policies in Europe.

Protests, Conflicts, and Implementation Failures

Urban policy, like any public policy, is a way to manage conflicts within society, to contribute to make and to legitimize a political order. They have to deal with interest groups, protest, resistance, and many implementation failures. The obsession with 'new urban policies' often reveals frustration with lack of results and failures.

This became obvious in the post-1968 period; when the 'urban question' took a different turn, Urban movements participated to class struggles, together with unions but outside factories (Castells, 1977). Urban mobilization concurred to claim for public goods, and enlarge the quest for better working condition coming from the workers movement to issues of quality of life and welfare conflicts. They also massively contested many large prestigious urban projects associating urban political elites and private developers and put forward alternative ways of live, including massive squatting movements in Swiss, Dutch, and German cities. This led to the development of urban policies addressing issues of historical centers renovation, environment, deindustrialization, race, and protest. More diverse urban policies also led to more interest groups, more organizations, more agencies, and more contradictions between different elements of urban policies within a territory.

Empirical researches on European urban conflicts, policies, and mobilizations have increased in the last years (Vitale and Podesta, 2011): neighbors, inter-ethnic, religious, xenophobic, and class conflicts including the most progressive and the most conservative interest groups and mobilization. Classic dynamics include contention for collective goods, reactive conflicts on urban planning, and contentious quest for public recognition. Current forms of urban contention seems independent from neoliberal policies, but affected by classical problems of private property, migration, eviction of poor neighborhood, lifestyles and individualization, density, commuting, the use of public spaces and transports, the 'entre-soi' of upper-middle classes, territorial inequalities and equalization claim-making, and localization of polluting infrastructure.

But neoliberal policies play a role. It is an ambivalent, twofold role (Brenner, 2013). On the one hand, neoliberal concerns deeply influence the means and goals of urban mobilizations. Some of the emerging actors in these mobilizations point to commodification and market virtues (critical consumerism, raves, craftsmen informal markets, third-sector lobbying for quasi-market). On the other hand, neoliberalism is attacked with distopic narratives, and collective action is organized against neoliberal policies with a major role played by political parties, and not only by grassroots organizations. One issue facing social actors is the difficulty to identify responsibility in urban policy, to blame actors: there are many experts, a strong judicialization; difficult translocal coordination; solution shopping, and some combination of policy ideas. Impacts of urban conflicts on neoliberalization relate to three main mechanisms (coalition building, emulation, and brokerage). Conflicts produce the weaving of alliances with some decision makers and some public bodies, changing power relationships, naming the public role of urban utilities and collective goods, thus affecting policy outcomes.

Classic public policy analysis (which is not rational choice) has also emphasized that policy implementation is central and that it is particularly central for urban policy for two reasons: the goals are usually very general (building an environment friendly, socially inclusive, economically dynamic, democratic, and culturally vibrant city region) and many interest groups are in competition. Urban policy has to be understood in the details of the operationalization (policy instruments) and implementation (Pressman and Wildavsky, 1974) where the winners, the losers, and the real goals are defined in the process of implementation. By contrast to large generalization, urban policy implementation often reveals contradiction, power relations, and weak top-down capacity of coercion (Laino, 2012). In most countries, the coherence of urban policy is an illusion created by discourse (and discourses are important). Often several urban policies, in contradiction with each other, are developed at the same time, with different organizations, different professional groups, or different levels of government in charge. Urban scholars too often take for granted national plans, and scenarios and maps to analyze urban policy when looking at organizations, rules, budgets, and interest groups is usually far more precise to explain the policy and its results. For instance, the renovation of historic city centers has been going on for decades in many countries, and the fact that the same policy is now labeled cultural policy, or policy to attract tourists, or social mix policy does not change much about the substance.

The point is not to argue that as far as European urban policies are concerned, *plus ça change plus c'est pareil* but to stress the fact that many policies are not implemented, that societies encompass many collective actors with resources mobilized to prevent change to take place, that urban policies are political activities thus include political actors who, at the same time, defend their interest and their constituency while pursuing some elements of common good. Public policy activities include important cognitive dimensions to label and 'sell' the policies that have to be critically examined that by contrast to strong constructivist views underlining ongoing changes or fragile assemblages always subject to changes; urban policies in Europe are also characterized by an important degree of institutionalization (rules, organizations, interests, budgets, ways of doing things) that are inherited and change slowly, due to lack of consistency, layers of policies added over the years, contradictions, and implementation failures. Beyond the labels, the goals, the substance of the policies are rather stable with a given set of repertoires of action.

Urban Policy Change

What has changed over the last decade is a growing emphasis on the environment, social cohesion and social mix, policing and the international dimension, both economic competition and integration of foreign born populations.

Changes do take place: the rise of environmental concern in urban policy is one example. All over Europe, European urban

policies, national urban policies, and policies development by urban governments include a vast array of programmes to limit carbon emission, and take into account environmental concerns. The political ecology of cities (Swyngedouw et al., 2006; Béal, 2011) has become an institutionalized field of urban policy, supported on the one hand by the rise of green party councilors in many cities and on the one other hand by giant utility firms (water, waste disposal) or information technology (IBM and the smart city) eager to sell massively expensive technological solutions to deal with water pollution, waste disposal, or the optimization of transport. Those policies include investment in recycling, limits to individual car transportation (in favor of bicycles or collective transport), reducing energy consumption of public building and activities, improving school food with local producers, setting environmental norms for building, or, more visibly, creating much heralded and visible 'econeighbourhood' much loved by ecologically concerned middle classes. Depollution of industrial land, brownfields, or the air is also on the card. Groups are enrolled, experts and consultants mushroom, national agencies are created, European networks of cities take the issue on board, political entrepreneurs rise, all sorts of citizen groups, scholars, and NGOs push in this direction.

Increasing spatial and social inequalities within European cities have made the question of poor neighborhoods more acute, a problem made more visible by the presence of immigrants. Various types of policies have been developed, usually with a strong integration element, in order to deal with those neighborhood: area-based policy, neighborhood policy, together with urban renewal have been tried out in particular to prevent riots, and systematic exclusion, or worse case of social segregation (Andersson et al., 2010; Epstein, 2012), in particular, in urban peripheries.

Policies do not change easily. Ideas about new policies and new concept travel change all the time and may have some contribution to changes (Peck, 2010; Theodore and Peck, 2012). In that sense policy mobility does matter and contributes to urban policy change but the more institutionalized the urban policy, the more difficult it is to bring changes based upon a new urban policy idea. Policy transfers are common in public policies but their impact is often limited. The idea of the compact city, developed in the Netherlands, gained prominence in debates all around Europe to limit suburbanization. Social mix policies have been at the core of fierce debate in urban research: do they contribute to the urban fabric or do they legitimize the colonization of middle classes and the domination of the poorest (Bridge et al., 2011)?

Macroprocesses also lead to deep long-term transformation of urban policy. David Harvey's seminal 1989 paper on urban entrepreneurialism is based upon his reinvigorated Marxist framework and analysis of the spatial fix of capitalism (Harvey, 1985, 1989). He explained how the rise of globalized capitalism was radically changing the logic of urban policy: competition between cities was the name of the game and urban policy had to be analyzed as the result of this disciplinary pressure on working and lower middle classes by a bourgeoisie and large economic interest taking advantage of the global competition between spaces. In Europe, urban policy shifted toward more entrepreneurial policies, destroying part of the existing capital (and social relations) in order to favor different conditions for capital accumulation. From a rather different perspective, Bob Jessop conceptualized the change as the end of the *national Keynesian welfare state* and the coming age of the *Schumpeterian globalized workfare state*. Analyzing 'the crisis of the national spatiotemporal fix and the ecological dominance of capitalism' (2000), Jessop's analysis was illuminating: national states were not just undermined by bottom-up political pressure leading to decentralization or metropolitan government, they were active and central in the restructuring of national spaces, to foster urban governance in order to accelerate the process of 'creative destruction' (Schumpeter) characteristic of capitalism. Urban policies were therefore to shift from classic planning, housing provision, infrastructure and welfare policies to supply side policies, development corporations, free tax zones, and competition. This crucial insight proved decisive to understand radical urban policy changes in Thatcherite Britain or in the US. Neil Brenner went further, building on the insights of Harvey and Jessop and also Neil Smith and Henri Lefevre to design his own model precisely linking the rescaling of the state, or statehood as he puts it, with the rise of urban governance. To sum up his argument: "'it is no longer capital that is to be molded into the (territorially integrated) geography of state space, but state space that is to be molded into the (territorially differentiated) geography of capital' and thus 'the goal of national, regional and local state spatial policies is no longer to alleviate uneven geographical development but to intensify it through the deployment of locational policies designed to strengthen the place-specific socio-economic assets of strategic, globally linked regions'" (p. 16).

National urban policy shift neatly reflects the trend. At the urban level, as was seen in the UK in the 1980s, more resources have been used to address the logic of competition to attract media attention, middle classes, capital, firms or public organizations in London or old industrial cities alike. That progressively also applied to cities elsewhere. Competition is not new as such; after all, all the countries saw fierce competition between cities to attract research centers, railway stations (nineteenth century), or airports but it is not regulated by political influence within the national space any more. Similarly and even more tellingly, national spatial policies have shifted: instead of dealing with regional inequalities, they support urban mega project and they shift resources to reinforce the prestige and competitive edge of capital cities. States use their capital cities as national champion for economic growth (Crouch and Le Galès, 2011). The more centralized the country, the more obvious the shift as evidenced in London, Paris, Copenhagen, Budapest, or Lisbon. Urban competition has become one important factor to explain urban policy change and that translated into financial transfers, public investments, and decreasing support for those left behind, in other words a shift "from regional development policy aimed at assisting backward areas to one aimed at improving further the performance of the most successful" (Crouch and Le Galès, 2011). Many in Britain have singled out this new form of capitalism (The phrase is due to urban policy scholar Alan Harding from the University of Liverpool) where the state invests in the capital and uses spectacular events, like the Olympic games, to legitimate large public expenditure in the capital city. Attempts to reorganize 'Great Helsinki' or 'le Grand

Paris' and the infrastructure projects associated to them (IT platform, new airport, new metro, international university) are no different.

The competition logic for urban policy is now promoted as end to itself: many city leaders publicly engage in the competition to attract the next international Expo (Milan, 2015 winning against Izmir, Turkey), a best practice award from the United Nations Programme of Best Practices to improve living conditions in human settlements, The EU green capital award (Vitoria in Spain after Hamburg and Stockholm), the European capital of culture (Marseille and Kosice before Umea and Riga). Honors and labels are like medals, classic instruments to create competition for prestige, orienting the conduct of conduct in the Foucauldian sense and legitimizing the UN or the EU. For urban elites, those labels are seen as a positive political symbol for elections and provide an opportunity to legitimize entrepreneurial policies, and benchmarking is an opportunity to create reputations, trust, and to attract investment or private public partnership.

Brenner has also worked with a group of critical political economy geographers to analyze the rise of neoliberalism, the characteristics of the paradigm, and the way it has translated into urban policies (Peck, Theodore, Brenner 2013) in order to carefully identify existing neo-liberalism and its incompleteness in most places.

There are lots of evidence to show how urban policies have been transformed, for instance, through the movement of privatization of services, utilities, and the introduction of quasi-markets; the financiarization of various urban majors actors (utilities, private developers, and even housing organizations) (Halpern and Pollard, 2011); the competition between cities justifying large investment in prestigious cultural projects, mega events (Olympic games), and emblematic buildings by star architects (Ponzini and Nastasi, 2011); supply side policies to support firms and economic development; more flexible land planning to allow for diverse project and private actors profit; gentrification processes favoring middle classes; new forms of policing including the control, exclusion, or surveillance of poor groups and immigrants; new ways to deliver policies through contracts to private firms (Raco, 2012); benchmarking between cities; massive urban renewal strategies (Epstein, 2013) or policies supporting gentrification. Whatever may be the dynamics between these different processes, globalization, capitalism expansion and financiarization, neoliberalization, and state restructuring matter for urban policy.

Urban policies, as most public policies, are the result of collective action where some of the actors have particular type of resources, political legitimacy, and capacity. The political sociology of urban public policy has emphasized the political role of other actors from social movements to NGOs and also from large firms, a classic theme in US urban studies which was less influential and fruitful in the Europe. Things are different now, thanks to globalization and deregulation process. Some actors in urban policies have accumulated so much wealth that the translation in power resources is becoming a threat for democracy (Crouch, 2011). Europe was for a long time rather behind this movement but things have changed: property markets, banks, and urban developments are now more and more part of international strategies from financial organizations.

In urban policy, giant utility firms have become massively influential actors, as EDF, Centrica, Gazprom, RWE, Eon, GDF Suez, ENEL, Veolia environment, or Iberdrola. They invest in different parts of the world in energy, the built environment, renewable energy in particular but also engineering, transport, or even water. The European market for utilities is estimated at around 800 billion euros per year. Capitalism is also urban capitalism and it takes different forms in Europe (Lorrain, 2005). Those firms have amalgamated to become globalized multiservice utility firms. Eon, the giant German utility group, had in 2012 a market capitalization of 27 billion euros and employed 75 000 people. EDF, the French electricity and utilities group, employs 150 000 people, with markets sales of around 65 billion euros in 2011. Most utilities negotiate some time length monopoly in delivering some services management or delivery, built infrastructure or energy with municipalities. Special funds dedicated to the financing of utilities have become major players of urban policies. Utility funds developed to finance the investment and the firms in utilities, energy, water, transport, waste disposal, and IT infrastructure who work with urban government. The deregulation of utilities, initiated in the UK by Mrs Thatcher's government, paved way for a formidable boom of the financing of utilities investment.

Top investors in property development are huge financial organizations, such as the Norway Sovereign Wealth funds, the leading investor in property development in Europe in 2012, but leading property development investors include the German fund manager Union Investment, the famous US private equity firm 'Blackstone,' or the real estate branch or top insurance companies such as Generali in Italy, Allianz in Germany, or Axa in France.

Urban policies in Europe deal with contemporary European cities. Urban areas all over Europe are dealing with the consequences of the crisis and financial cuts are limiting their otherwise important investment capacity. At best they enjoy slow growth but some are facing deep crisis. Western Europe's classic largest metropolis (i.e., London and Paris, around 10 to 12 million inhabitants) are not in the top 20 in the world any more and aging is a growing concern. By contrast, Istanbul and Moscow are taking over as major development centers on the other side of the continent. Despite the welfare state, inequalities increase, riots regularly take place, in particular in former colonial countries (London, Paris) or not (Stockholm), or against the crisis in Athens, Madrid, or Barcelona. The EU has not delivered in terms of regional and urban policy and the much heralded change toward a more sustainable development and less energy proned growth model is proving slow and difficult. Utilities and private developments are financiarized. Democracy is under pressure from large global business firms, extreme right parties, and general decreasing engagement with politics. European cities and urban areas are becoming more ethnically diverse, thanks to immigration, even if the social models are still robust and cities experiment democratic participation (Kübler, 2012). Since the 1980s, at least until 2010, most Western European cities enjoyed demographic and economic growth; even former industrial cities joined the trend with a few exceptions in Germany, Italy, or the UK. But Eastern European cities went the other way in the aftermath of post-1989 economic deindustrialization even if the capitals

now recover. The EU urban policy has not been included and for one good reason: after a slow emergence a decade of important initiative led scholars to expect the development of an ambitious Urban policy, the dog did not bark. The liberal turn of the EU in the late 1990s marginalized the whole regional policy aiming at reducing inequalities. Enlargement became an excuse to get rid of the urban policy and the 'mainstreaming' of EU urban policy meant residualization (Atkinson and Eckardt, 2004; Halpern and Le Galès, 2011).

European cities are part of the restructuring process of a continent searching for a different model. Urban policies in Europe are part of this work in progress, if progress is the right word. But the economic crisis and what looks like a decade of austerity is deeply undermining European cities and urban policies alike.

Urban Policy in North America

Michael B Teitz, University of California, Berkeley, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Urban policy in North America comprises a blend of historically established laws and government policies together with newer efforts to address urban problems. In the former category are key social agreements, for example, that urban development will be primarily carried out by the private sector, constrained only by planning laws that are mostly in the domain of local and state governments. Examples in the latter category include efforts to solve specific urban problems such as inadequate and unaffordable housing for low-income populations, or to respond to infrastructure deficiencies in transportation. All three countries in North America – the United States, Canada, and Mexico – are federal in their governance structure, so policy is necessarily distributed across the levels of government. As a result, central government plays only a limited role in key aspects of urban growth, though in Mexico there is a stronger tradition of centralization of policy. Within this framework, urban policy is diverse, but falls into three broad groupings. First, land use and development underpin urbanization; policy in these areas has existed from the earliest days in all three countries, exemplified by regulation of urban form. In North America, such regulation has, to varying degrees, supported market driven development. Second, urban policy deals with management of key functions, exemplified by transportation, public health, utilities, and environmental quality. Such policy occurs at all levels of government. Third, urban policy addresses social issues that have varied over time from the acculturation of immigrants, to poverty, housing, and race relations.

Urban policy in North America is something of an anomaly. In all three countries – the United States, Canada, and Mexico – most people live in urban areas, yet national governments have few policies explicitly identified as urban, even though most national domestic policies have powerful urban implications. Urban areas contain their own local governments within larger federal and state structures, and those governments pursue the welfare of their inhabitants and other organizations within their boundaries. States and provinces occupy an intermediate role within the federal structure of each nation-state, establishing the ground rules for much that urban governments may do while intervening directly. Although urban policy has come to be identified particularly with some sets of issues, notably those to do with land use, housing, transportation, poverty, and racial segregation, in fact it is much broader than this. Indeed, it may be argued that many of the most important components of urban policy in the countries comprising North America are scarcely visible. Cities are the most dynamic form of human social organization. Urban policies reflect fundamental social agreements about how cities and towns continue to be built and transformed and how their inhabitants relate to each other. Only when those understandings are challenged does the visible portion of urban policy emerge, usually in the context of political and social conflict. Resolution of those conflicts has been a part of urban life throughout history and it will continue to be so.

'Urban policy' may take on two closely related meanings, depending on how the term 'policy' is understood. In a broad sense, 'policy' denotes a general and high-level guide to decision and action, particularly by governmental or other public entities. In this case, urban policy should be seen as comprising general principles that guide public action in urban areas and frame the issues associated with them. For example, urban development through market processes, and support of home ownership have been such policies in the United States for the past century. 'Policy' also specifies a definite course of action selected from among alternatives to realize specific goals. In this sense, 'urban policy' refers to such courses of action in relation to urban areas and issues, especially in the public realm. An example might be the policy of supporting home ownership by making mortgage interest tax deductible. In practice, it is difficult to disentangle the two, especially in advanced societies, where most of the population lives in urban areas. Furthermore, the diversity of urban areas within a national political system, be they metropolitan regions, cities, or smaller urban places, engenders specific forms of complexity that are reflected in public policy. Thus, to understand urban policy, it is necessary to see how public decisions are formulated, as well as to examine the character of urban policies in both their general and specific senses.

Public Action in Relation to Urban Areas

The organization of public action reflects a profound dilemma associated with geographically differentiated places whose populations have political power. Metropolitan areas, cities, and other urban entities are the most dominant such places in our time. Considerations of technical efficiency often suggest that public action should be shaped by functional requirements, rather than in accord with governmental structure (examples are transportation, public utilities, and public safety). Such function-based structures might be seen as a 'vertical' form of organization, in which a particular function is managed coherently to take advantage of the economies of scale. Most national states have ministries that reflect such a functional division, as do lower levels of government. In strongly unitary states, such national ministries extend their reach to virtually all aspects of life, even at the most local or individual level.

Society, however, comprises much more than the nation-state, being a vastly complex structure of social, economic, and

political relationships among individuals and groups. The reality of everyday life engenders strong relationships in a 'horizontal' form, crosscutting functional concerns and focusing on place itself. Such 'place-based' concerns are accentuated where people in subnational communities have the political power to express their collective desires, even though they may run counter to national concerns expressed through vertical forms of organization. Democratic societies in which legislatures are elected on a geographic basis are particularly likely to express such horizontal pressures. However, the fundamental social organizational forces that create subnational communities are present everywhere, with concomitant tensions between the vertical and horizontal, the functional and the communal, at all levels of government.

One solution to this dilemma is a federal system, in which legislative and executive responsibilities are explicitly allocated to different levels of government, usually associated with accompanying geographic disaggregation of the national space. This is so in all three countries in North America. Conventionally, systems of this type exhibit at least three formal levels of government, national, state (also called regional or provincial), and local, with the latter often further subdivided. Urban areas are rarely national in scale or scope, though Singapore provides an important exception as a city that is a unitary state, albeit with local forms of administration within itself. Urban areas at the first level below the national in a federal system are also relatively infrequent, though Mexico City and Washington, DC, are principal examples. Even there, the capital is a unique political entity rather than simply a state within the federal system. Thus, most urban areas in explicitly federal systems fall under the jurisdiction of local governments.

Although urban areas are geographically local in nature, urban policy is not also essentially local. To the contrary, cities are intricately involved in national politics in urbanized societies. Many strands of national policy affect urban areas or are intended to respond to the concerns of their inhabitants. The formation and execution of urban policy occurs at all levels of government. In addition, many policies that deeply affect urban areas and their inhabitants are couched in terms of other policy domains. Major governmental ministries or agencies whose explicit mission is to shape urban policy are rare. Nonetheless, urban places are both the target of many explicit policies, while also the recipients of the consequences of others. It is often difficult to distill the urban policy implications of policies formulated in other fields.

Urban Policy in North America

North America is a continent comprising three separate nation states, each with a distinctive history, its own cultural and demographic makeup, and its own economic, social, and political system. Nonetheless, Canada, Mexico, and the United States do have much that is common in their forms of urbanism, their governance, and the policies they have evolved. All three countries are highly urbanized, although Mexico has a somewhat lower proportion of its population living in urban areas, reflecting its status as a less-developed economy. In each country, market forces drive urbanization, though the extent to which they are regulated varies substantially. Cities in each are shaped by the dominant technologies of our time, especially by the automobile as the primary means of transportation. Demographic changes, especially immigration and aging are affecting urban areas in each country. Nonetheless, there are important themes of urban policy in each. Critical to understanding those themes are the categories of public policy involved and the governments that addressed them.

Although 'public policy' is a widely used term, which now drives political debate, as well as graduate and professional education and research, it is seldom voiced in legislation. Much urban public policy, in fact, may be settled, broadly accepted, and challenged only when conditions change sufficiently to lead to questions being raised about its validity. Urban policy, in this view, is something like an iceberg, much of which is virtually invisible.

Urban Policy as Land Use and Development

Consider the fundamental question of how urban areas in most of North America are designed and built. Current policy debates concerning land use planning, urban sprawl, and transportation infrastructure investment are shaped by long agreed public policy that urban development should be carried out by private investors, regulated by government, and in part supported by public investment. Europeans established this policy in the early years of settlement of North America, even though the first settlements were far from pure capitalist enterprises. As colonies of Britain, the Netherlands, France, and Spain, they were intended to benefit their parent countries, and to varying degrees they were rigorously regulated and their forms prescribed. Some of this heritage carries over, especially in Mexico. Nonetheless, in the United States, especially, there had emerged by the early nineteenth century a distinctive form of settlement that was to define the American form of urbanism, namely the grid-plan.

The urban grid, a rectilinear structure of streets, was the physical expression of a fundamental policy that urbanization would be market driven, privately organized, and minimally regulated. It enabled two key elements necessary for such a process to work. The first was the creation of easily laid out and marketable lots that could be sold speculatively to buyers at a distance. The second was the easy expandability of the urban structure, simply by adding further streets and subdivisions as the market expanded. Thus, a distinct and recognizable form of American city emerged, speculative in its origins, highly adaptable to changes in growth and technology, and based on the conception of land as a marketable commodity. Even when the grid was replaced in the twentieth century by the curvilinear streets of the suburb, development remained a function of the private market. The suburb, with its stronger appeal to the consumer's sense of aesthetic quality and lifestyle choice, necessarily expanded the realm of public or quasi-public regulation, but it was equally the product of private, speculative development. With this shift, however, in the United States came major public policies that have supported this form of urbanization, notably the federal funding of major highways, and the deductibility of mortgage interest, the latter justified by an explicit policy of encouraging home ownership rather than rental tenure. The most recent challenge to suburban forms of urbanism, by neo-traditional or 'New Urbanist' critics, calls

only for a change in the way in which urbanization is treated by regulation and taxation. Only relatively rarely in modern American history has government attempted directly to create urban places, even though national, state, and local laws have fundamentally shaped urban settlement patterns. United States' efforts to build new towns during the Great Depression of the 1930s were unusual in this respect and they failed.

Clearly, this account simplifies a complex, continental scale reality. The legacy of Spain in Mexico was one of a much more centralized, class defined, and bureaucratic society. Mexican urban development reflected those facts in its slower growth and more constrained forms of urbanism. Similarly, development in Canada reflected both the earlier French centralizing influence and the British legacy of unitary parliamentary government, albeit grafted onto a federal system in which the provinces were relatively strong. It is no accident that public control of urban development in both Mexico and Canada remained historically much stronger than in the United States, yet in both countries cities are not built by governments.

The idea that urbanization is market driven has had powerful consequences. Paradoxically, the market itself implies public constraints. No market functions without some prior structure of behavior or public order; some constraints must be established for markets to function at all. For urban policy, this implies public regulation of the urban development process. The nature and locus of that regulation has defined many of the key urban policy issues in North America over the past 100 years. In the United States, control of public policy is ultimately vested either at the level of the states or of the federal government, depending on the Constitution and its interpretation by the Supreme Court. With respect to land use, control is generally agreed to rest legally at the state level, although the basic legal doctrines that support land use regulation rest on constitutional decisions that are national. In fact, states have delegated land use regulation to local governments under a variety of names. California, for example, delegates the power under the doctrine of 'Home Rule.' On this legal basis, aided by a long history of piecemeal settlement and independent formation of urban places, US urban policy toward development and change is played out at the most local level.

This situation contrasts sharply with that in many other advanced countries, notably in Europe and Asia, where state or central governments play more centralized roles in land use planning, regulation, and development. Canada and Mexico also present substantially more centrally regulated versions of urban development. In Canada, cities in the central and western provinces tend to look more like those in the United States. The eastern provinces have a stronger tradition of central control, though always empowered at the provincial level. Toronto's ability to control its suburban development contrasts markedly with any US city, but a change in political complexion at the Ontario provincial level has had substantial implications for the city's policy. In Mexico, until very recently, with a single-party state, local control of development was limited. Although state or central governments did not always have the capacity to enforce their will more than intermittently over economically or politically powerful local groups, the tradition of central government finance and fiat remained powerful. How this has evolved in the first decade of the twenty-first century, as the political monopoly of the Partido Revolutionario Institutional (PRI) has ended will be discussed later.

Urban Policy as Functional Management

Local power over development has major implications for urban development, particularly when viewed from a functional perspective. For decades now US observers and advocates have argued that urban problems of transportation, energy, utilities, and environmental quality require the political ability to act at a regional level. Again and again, such arguments have been turned back as localities have refused to form larger regional governments or to cooperate in accepting land uses that they deem undesirable. That refusal has been encapsulated in the term 'NIMBY' ('Not in my back yard'), which has become both a rallying cry for control by local neighborhoods in the face of larger economic and political forces, and a term of opprobrium conveying selfishness and exclusion. Nonetheless, metropolitan areas cannot be built and cannot operate at a high level of amenity and income without necessary functional efficiency. One widely employed means around the problem has been the creation of single-purpose special districts, for example, to handle water supply. These are typically limited in their range of action and their ability to override local decision making. They are established by state law, but with the clear requirement that local political representatives support their formation. In recent decades, some entities of this type have also emanated from federal governments in all three countries.

Management of air quality is good example of such urban policy, illustrating both its urban character and its placement within another organizational realm. Awareness of the dangers of air pollution has a long history in urban areas, but its modern manifestation in the United States may be dated from the passage of clean air legislation by the city of Pittsburgh in the 1950s and the enactment of state and federal air quality standards and legislation in the 1970s. At first, efforts to improve urban air quality focused on stationary sources of pollution, especially industrial sources such as steel mills and oil refineries. As they were controlled, however, it became apparent that the single greatest source of air pollution was from mobile sources, especially private automobiles. In metropolitan areas and cities such as Los Angeles, dirty air was identified as a contributing cause of serious public health problems and reduced quality of life associated with smog. Clearly, these were regional and in some cases interstate problems. The federal government's response was to treat environmental quality by regulatory legislation and the formation of the US Environmental Protection Agency in 1970. State governments reinforced the effort with similar legislation.

Air quality degradation by automobiles can be countered in many ways, including regulating the emissions permitted, increasing the cost of driving, providing incentives for use of cleaner vehicles, and changing the way in which urban areas are structured so as to reduce the number of miles driven. Any of these policies are conceivable, but the specifics of implementation differ among them. Furthermore, the mode of intervention might have a great deal or very little relationship to urban areas themselves. Regulation of automobile emissions through national specification of permissible technologies is

only indirectly urban in character, and its effectiveness will vary with the standards applied from place to place. On the other hand, consider the problem of regulating development as a means to control emissions in metropolitan Los Angeles. Although both federal and state agencies have regional offices, neither would typically be able to carry out such a policy effectively at the local level. To do so for the metropolitan area required also a regional agency, in this case, the South Coast Air Quality Management District. This agency, established directly by the state, legally has the power to override local development decisions. However, in the face of overwhelming political opposition to such actions, which would violate home rule, it has been reluctant to do so, preferring to employ its regulatory powers in other directions. Alternative air quality policies may have similar goals, but their urban manifestation may be quite dissimilar.

This story of policy directed toward urban problems, defined on a functional basis, and legislated and implemented at multiple levels of government can be found again and again in North America, as it can elsewhere in the urbanized and urbanizing world. Apart from being much worse than in Los Angeles, air pollution in Mexico City presents much the same set of problems. In transportation, public health, housing, water supply, wastewater disposal, garbage removal, and public safety, governments have been attempting to find solutions within their own financial and political situations. It is not a new phenomenon. From the beginning of the industrial revolution, much of what we recognize as urban policy has been driven by attempts to deal with the dysfunctions of the industrial process. This process occurred a little earlier in Britain than in most of Europe and North America, but once on course it has barely slackened. Some urban concerns, of course, are much older. For example, laws to prevent disastrous fires by prohibiting wooden buildings may be found in the very earliest records of urbanization. However, the emergence of systematic urban policies really dates from the nineteenth century.

For early industrial cities in North America, the most urgent issues were public health, public safety, and transportation. The previous section indicated how the use of a planned grid permitted both a functioning land market and lines of transportation. Although the cores of cities were often congested, especially where, as in Boston, their cores were essentially unplanned, they could function with pedestrian and horse-drawn transportation before the advent of the railroads. However, such cities were necessarily densely built, outran their water supplies, and had primitive sewage disposal. Frequently, they endured epidemics, notably of cholera and yellow fever. As epidemiology evolved, the importance of clean water and sewerage became evident and the first great modern age of urban policy began. Although the delivery of pure water was, at first, a privately financed and run form of enterprise, it soon became a municipal monopoly, as did sewerage. Provision of electric power and gas, on the other hand, primarily remained private enterprises in North America, with a few minor exceptions. These utilities were regulated after the turn of the twentieth century in order to limit their monopoly power. Public safety became a key municipal function with the creation of police and fire forces in the nineteenth century and has generally remained so.

Beginning with the development of urban trolley lines and railroads in the nineteenth century, transportation investments have played an especially critical role in urban policy over the past 200 years. Although streets and street maintenance have been primarily managed by local governments, the provision and regulation of transportation has involved both private markets and public entities and governments. In the United States, most public policy in this realm was enacted by state and local governments throughout the nineteenth and early twentieth centuries. The ability of dense but growing cities to expand depended on fast and reliable forms of transportation so long as employment remained centralized. Privately run trolley lines, buses, subways, and commuter railroads, operating under local or state charters, provided a workable, if often uncoordinated solution. Later, many were consolidated under public ownership. Together, they enabled development of the suburbanized city of the early twentieth century, brought to full flower by the automobile. With the advent of automobiles, the focus of public policy shifted from private investment in infrastructure to public investment in highways, funded in large part by taxes on the sale of gasoline. National government engagement in transportation within cities remained minor until the 1950s. By that time, the invention of the freeway had raised the cost of new investment beyond the capacity of both local and state governments.

Large-scale federal entry into the process began with the creation of the Interstate Highway Program in the 1950s. Despite its formal purpose of enhancing national defense by providing high-speed, controlled-entry highways linking the entire country, the Interstate system played a substantial role in urban development through the second half of the twentieth century. By the year 2000, urban freeways ran both through and circumferentially around every major urban area in the United States, fostering suburban decentralization of cities across the continent. Similar freeway development took place in Canada and, more recently, has been occurring in Mexico. Although there has been much debate about the precise intent and impact of the Interstate system on US cities, there can be little doubt that the availability of federal funds significantly enhanced suburban development in the past 40 years. Whether these were conscious policy choices and whether this was the primary cause of the decline of central cities, discussed later, cannot be demonstrated. Given the rapid growth of population, productivity, and income, together with consumers' desires for single-family housing and automobile transportation, it seems likely that economic and political pressures would have had similar effects, whether or not the federal government was involved. Nonetheless, this period saw the entry of federal policy into urban transportation in a major way. It remains there today, although the nexus has shifted. The past two decades has seen a resurgence of political support for urban mass transportation, driven by the perception that the freeway solution is either too costly or too destructive of environmental quality to be sustained. This perspective parallels the critique of the suburb and urban sprawl discussed earlier. As a result, federal transportation funds now include substantial subventions to mass transportation – buses, light rail, and commuter rail in metropolitan areas. While the effectiveness of this shift is

being debated, it now appears to be an entrenched element of national policy toward urban areas.

Urban Policy as Social Policy

Since the 1960s, urban policy in the United States has not been primarily associated in the media and public debate with the issues discussed so far, though the recent resurgence of concern about urban sprawl and climate change has shifted attention back to the effects of urban growth. Rather, for several decades, urban policy has been primarily identified with problems of poverty, racial discrimination, segregation, and the decline of central cities. As is true in so many other instances, such a definition of urban policy is not new. It emerged in tandem with the industrial city in the nineteenth century, when low wages, intense overcrowding, dilapidated housing, crime, social disorganization, and disease combined to generate a new form of urban slum. The public health effects of industrial urbanism first engendered policy responses that were engineering solutions, especially in the form of potable water supplies and waste disposal. Epidemics and infectious diseases, such as tuberculosis, also required medical responses, which took the form of public hospitals and health services. Crime problems engendered police forces and prisons.

However, by the late nineteenth century, the fact that so many of the new urban populations in the United States and Canada were immigrants led to concerns for public safety in a larger sense, namely the stability of the society itself. Public education became a key element of local urban policy, its intent being both to provide a literate and capable labor force for the expanding economy and to ensure that children were able to speak English and become acculturated into society at large. Fears that immigrants would bring with them European socialist ideas and form labor parties were not unjustified, despite the fact that they were not realized. The momentum for these policies was certainly national in scope and linked to the prevailing sense of the United States as an emergent imperial power on a world scale. However, their realization was almost entirely at the state and local levels, where governments and influential voluntary groups were at times almost indistinguishable.

Poverty presented not only a risk to the health and social position of the affluent in American cities, it also affronted their belief in the United States as a place of freedom and opportunity. Efforts to help the 'worthy poor' raise themselves out of poverty took many forms, of which the Settlement House movement is the best known, evolving into forms of assistance associated with the social work profession. This movement also provided an early means for women of higher social status to become active in professional and social realms. Thus, by the early twentieth century, many believed that urban poverty called for effective governmental and voluntary actions.

A key realm of response was housing, and it is here that the largest challenge to the idea of urban development through the market emerged. The slum was perceived in many ways, but the vision of grossly overcrowded, unhealthy, dilapidated housing was intrinsic to all of them. Observers and critics of capitalism had noted the inability of markets to provide adequate urban housing from early in the industrial revolution. Public efforts to regulate construction or management were largely ineffectual, however. By the end of the nineteenth century in the United States, as in Britain and Europe, there had emerged two competing policy responses. Public regulation of housing quality took the form of building and housing codes, enforced by local bureaucracies. Those who saw regulation as insufficient or ineffective called for direct public or non-profit ownership and rental of housing for low-income families. Market advocates opposed both.

The twentieth century has seen the parallel evolution of these approaches to low-income housing policy in all three countries of North America. Mexico, which was undergoing a revolution and installation of a one-party state, probably exemplifies the highest level of commitment to public provision. However, the lack of resources due to underdevelopment, and the mistaken effort to adhere to unrealistic standards, ultimately ensured that public housing would become only a very limited part of its mass urbanization. In common with other developing countries, urbanization for the poor primarily meant informal housing on the margins of major cities. Canada, with a stronger tradition of government intervention, though varying greatly across the provinces, has also adhered to policies that give greater weight to provision of low-income housing. In both the United States and Canada, the tradition of local regulation continues, with rising standards and incorporation of new areas of oversight. In the United States, a determined effort to create a public housing program in the 1930s saw its culmination in the Housing Act of 1949, which led to construction of federally funded rental housing for the poor in most cities. However, the program became discredited, in part because of social problems emanating from its increasing racial segregation and focus on the very poorest populations, and in part because of insufficient funding to maintain and control high-rise housing that was ill-designed for its purpose. In a major shift of federal policy affecting cities, the program was largely replaced after 1974 by a low-income rental subsidy, which remains the basis of federal policy in this area. As a result, direct provision of new housing for the poor has switched toward the nonprofit sector.

Entangled with housing and poverty policy, especially in the United States, is the issue of race. American cities have long been segregated, both by race and income. African-Americans were confined by economics and social pressure to limited residential areas within cities. This phenomenon was exacerbated by major migration from the rural south to northern cities throughout the first half of the twentieth century. While that migration resulted at first in opportunity and rising incomes, by the 1950s there had also emerged ghettoes of African-American and other minority groups in poverty, in which serious social problems persisted. This process was exacerbated by the out-migration from older cities of white middle- and working-class populations seeking a suburban lifestyle and impelled also by race-based fear and prejudice. As a result, cities' financial capacity to address the needs of their populations declined. Education and public service quality diminished, which reinforced the migration. With improvements in civil rights during the 1960s, yet with racial discrimination still widespread, the contrasts between racial groups' aspirations and achievement burst out into urban civil disorder on a massive scale. Large areas of cities including Detroit, Los Angeles, and Washington, DC, were devastated.

The question of appropriately responsive policy is almost paradigmatic of urban policy in general. On one hand, efforts were made to improve incomes and opportunity through broad programs, such as those for education and job training. On the other hand, there were efforts to empower local communities through a variety of supports and incentives for the formation of community organizations. The so-called War on Poverty of the 1970s, exemplified both kinds of policy. It certainly led to the formation of new political networks and organizations among the urban poor, with long-term results on the racial and ethnic makeup of local politics. However, the position of the poorest and most socially disadvantaged populations improved little, if at all, in the face of a widening gap in the income distribution at large and a decline in the demand for unskilled labor. Increasing crime and social disorganization associated with rising drug use also contributed to the problem. With falling national rates of economic growth, budget stringency led to the withering away of urban poverty programs. In the mid-1990s, these issues were once more addressed by national policy, operating this time through the medium of the welfare program, and especially its support for unmarried parents. Insistence on entry into the labor market has reduced the level of dependency substantially, but the results have yet to be tested outside a boom economy.

Urban Policy in the Twenty-First Century

Cities as physical and social artifacts last for centuries, while policies come and go. Nonetheless, new physical and social challenges, and shifting political configurations do force change. After the first decade of the twenty-first century, it seems clear that both are at work. For North American cities, perhaps the greatest challenge is that presented by the prospect of major climate change through the process of global warming. Cities will be affected in a multitude of ways, ranging from rising sea levels to extreme temperatures and catastrophic weather events. The United States as a major emitter of greenhouse gases has made little national effort to address the problem, but states and cities in all three countries have begun to encourage efforts both to reduce carbon emissions and to prepare for the adverse consequences of climate change. California is especially notable in its enactment of legislation, together with administrative actions to reduce carbon dioxide. Many local governments have been pursuing policies toward both prevention and mitigation of the effects of climate change. It is striking that in this instance state and local governments are ahead of their national counterparts, but they are a minority.

This lack of action coincides, not accidentally with a shift to the right in the political environment in all three countries during the first decade of the twenty-first century. In the United States, that shift stalemated any effort to ratify or implement the Kyoto treaty on climate change, even as the federal government cut urban programs, especially in low-income housing, reinforcing the drift toward higher-income inequality. However, overall racial segregation declined as African-Americans and Latinos moved to the older, inner suburbs. At the same time, the tragic events of 11 September 2001 led to a huge increase in efforts to ensure security, with funds being poured into urban police and surveillance. In Canada, a conservative government came to power and similarly scaled-back programs directed toward urban issues after a long period of liberal domination. Income inequality has increased, along with residential segregation and gated communities. Perhaps the most dramatic change came in Mexico, where the PAN defeated the PRI after more than 40 years of one-party rule. Urban policy, particularly toward housing shifted toward the market, with an emphasis on middle- and working-class home ownership. New institutions for housing mortgage finance and land provision resulted in a large increase in overall supply, but at the cost of increased income segregation. Whether this shift to the right will survive the effects of the global financial crisis starting from 2008 remains to be seen, but there can be no doubt that it has constituted a major change in the environment for urban policy in North America.

Abstract

After nearly four decades of research and efforts at policy reform and program intervention, the number of persons in poverty is increasing and persons in poverty are becoming more and more concentrated. This article provides an overview of the history of poverty in America, its causes, and indicates why scholars and policy-makers should be concerned. The article concludes by calling for a more comprehensive approach to the solutions of poverty – one which takes into account the structural sources of poverty, its multigenerational roots, and the link between individual neighborhoods and regions.

Opinions differ regarding what causes poverty in America and why it seems to be concentrated in certain areas. Regardless of these differences, there is a relatively new focus on urban poverty and an agreement that the number of persons in poverty is growing as is the concentration of poverty in urban neighborhoods.

Poverty in America

National interest in poverty was first triggered when John F. Kennedy, while running for president, was taken on a tour of poor areas in the rural south. What he and his entourage saw was staggering: children with bloated bellies, families living in tar paper shacks, high rates of unemployment, and illiteracy. In short, the other America – families living in a state of poverty, the likes of which most Americans had never seen. This experience so affected the young presidential aspirant that he vowed, if elected, his administration would do everything within its power to address issues of poverty in America.

During the 1960s, politics and the publication of Michael Harrington's *The Other America* (1963), helped to focus the nation's attention on the plight of the poor in urban areas. President Johnson, taking office after Kennedy's assassination, launched the 'War on Poverty' in an attempt to have the federal government significantly address problems of poverty. However, due to the Vietnam conflict this effort was short lived.

It wasn't until the publication of James Wilson's *The Truly Disadvantaged* (1987) nearly two decades later, that interest in poverty was rekindled. Wilson's book sparked a flurry of research projects seeking to provide answers to such questions as: how widespread is poverty in America, what causes poverty, where is poverty most severe, what types of individuals and/or households are likely to wind up in poverty, what does being raised in poverty do to people, can people escape poverty, and perhaps most important, what can be done to reduce the incidence of poverty, and who should be responsible for addressing poverty issues? The results of most of these studies have revealed that poverty in America is not limited to rural areas. Every major city in the USA contains poverty neighborhoods and, in spite of growing economic prosperity, more Americans find themselves increasingly concentrated in poverty neighborhoods.

A person in poverty is defined by the United States Bureau of the Census as one whose total family income falls below a federally defined level. This level varies according to family size and is adjusted annually for inflation. In 2000, for example, the poverty threshold for a family of four was $17,463. The poverty rate for a particular neighborhood is determined by dividing the number of poor persons who live there by the total number of poor and nonpoor persons. Census tracts are used as the geographic basis for identifying the location of poverty neighborhoods. Researchers differ on the cut-off level for defining poverty neighborhoods. The range is from 20 to 40%, with the higher level being used most commonly. While different names have often been ascribed to poverty neighborhoods, Jargowsky (1977) refers to African-American high-poverty areas as ghettos, while barrios describe Latino high-poverty neighborhoods, and slums are poverty neighborhoods comprised primarily of whites.

What Causes Poverty and Why Does It Seem to Be Concentrated in Certain Neighborhoods?

A number of different explanations for what causes poverty and why poverty appears to be concentrated have been put forth. Some of these include: discrimination and segregation, immigration of rural farm workers from other countries to cities in America, the poor quality of inner-city schools, crime and the prevalence of drugs, white flight, and the emergence of a global economy.

The Creation of Ghettos and Barrios: The Role of Segregation

During the 1940 and 1950s, the USA underwent a rapid expansion of its industrial and manufacturing sectors. African-Americans seeking to improve their quality of life migrated in large numbers from the south to major urban growth centers throughout the USA. Segregated housing, restrictive covenants, and zoning practices forced many of these African-American migrants to seek shelter in older sections of cities. Segregation and discrimination also limited employment and advancement opportunities, which in turn impacted earning power. As a consequence, African-Americans were disproportionately concentrated in low-income and often poverty neighborhoods

called ghettos (Drake and Cayton, 1945; Clark, 1965; Dubois, 1967). Even after the passage of Title VI of the Civil Rights Act of 1964 and Title VIII of the Civil Rights Act of 1968, real estate agents, mortgage brokers and lenders continued to make it difficult for African-Americans to acquire housing outside of inner city areas. As a consequence, African-Americans, unlike their white counterparts, have much lower home ownership rates, one of the key ways Americans accumulate wealth (Bullard et al., 1994; Oliver and Shapiro, 1995). Massey and Denton are two scholars who maintain that racial segregation and not economic segregation have played a major role in the continued growth of ghetto poverty (Massey and Denton, 1993).

During the 1970, 1980 and 1990s, a large number of immigrants from Latin America, in particular from Mexico, have come to the USA. To a certain extent, these immigrants find themselves relegated to poverty areas or barrios, much like African-Americans did before them. More recently, immigrants from various Asian countries, particularly Vietnam, Cambodia, and Laos have been moving to American cities. In 1990, foreign-born residents constituted 10% of all those living in concentrated poverty areas, up from 3.5% two decades earlier (Mincy and Wiener, 1993, Table 6). As of yet, no single term has emerged to describe Asian poverty neighborhoods. Although references to China Towns, Little Tokyos, and Little Vietnams often imply similar conditions to ghettos and barrios. Like African-Americans, the new immigrants also find that their poverty neighborhoods suffer from inferior schools, high crime rates, inadequate housing, and limited employment opportunities. Language barriers and low educational achievement seem to be key factors contributing to the concentration of these new immigrants in poverty neighborhoods.

While researchers have easily identified poverty neighborhoods with a predominance of racial minorities, that is ghettos and barrios, few predominately white poverty neighborhoods or slums are evident in metropolitan areas. This is not to say that there are no whites in poverty; quite the contrary, the largest number of individuals in poverty are whites. It is just that poor whites are distributed throughout cities and not particularly concentrated in certain neighborhoods.

Social Mobility

Social mobility, or as Wilson (1987) calls it, "neighborhood sorting," is another reason often put forward to help explain the growing concentration of urban poverty. There are two dimensions of this concept. The first focuses on white flight; that is, as more and more minorities move into urban areas, better educated and more affluent whites move to the suburbs. Reasons most often given for this out-migration of whites from central city areas include: a desire to provide better educational opportunities for their children, safer neighborhoods, better and cheaper services, more neighborhood amenities, and the ability to realize greater return on their investment in housing.

These same interests are propelling the move of middle-class African-Americans from inner city areas, leaving poor African-Americans behind. The consequence is, further concentration of poor people in central city poverty neighborhoods (Wilson, 1987).

The Impact of the Global Economy

More recent literature has focused on what role deindustrialization, brought on by a growing global economy, has had on both increasing the number of persons in poverty and the growing spatial concentration of poverty (Bluestone and Harrison, 1982). The growth of new jobs is occurring faster in suburban areas than in inner-city areas. This makes it increasingly difficult for residents of poverty neighborhoods to acquire employment. Kain (1968, 1992) calls this the spatial mismatch phenomena.

Rapid job growth in the service sector has reduced the impact of some losses of industrial employment. However, these jobs tend to pay relatively low wages with few, if any, benefits. This often means that, even though individuals residing in poverty neighborhoods can secure work, the jobs they obtain do not provide adequate income or sufficient benefits to lift them or their families out of poverty. Thus, there are a growing number of working poor residing in poverty neighborhoods (Pastor et al., 2000; Bernstein et al., 2000).

The Significance of Regional Economic Growth and Poverty Neighborhoods

Some of the more recent literature suggests that there is a link between the size and growth of poverty neighborhoods and the robustness of a region's economy. Jargowsky, for example, shows that a rise in overall metropolitan mean income resulted in sharp declines in ghetto poverty concentration among African-Americans (Jargowsky, 1977). Similarly, Pastor et al. found in 74 regions throughout the USA that regions which performed best economically were also ones that either reduced inner-city poverty or reduced the rate of growth of poverty neighborhoods (Pastor et al., 2000).

To date, the most comprehensive work examining the causes of poverty can be found in *Poverty and Place: Ghettos, Barrios, and the American City* by Paul Jargowsky. Unlike previous studies which are locale specific, this study examines national poverty data. Jargowsky finds that structural changes in the economy have in fact adversely affected those with lower educational levels and job skills by reducing their wages. He also finds that deconcentration of employment further reduces the possibility of these individuals finding work and that the flight of higher-income individuals from poverty neighborhoods is an important factor in increasing neighborhood poverty. However, he could not find any evidence that strongly supports the notion that segregation plays a direct role in the recent growth of poverty neighborhoods. Jargowsky concludes by suggesting that neighborhood poverty is the

> predictable result of the economic status of minority communities and the degree to which minorities are residentially segregated from whites and from each other by income.
>
> Jargowsky, 1977: p. 19

Why Is It Important to be Concerned about Urban Poverty?

One of the reasons for the concern with urban poverty is that place and neighborhoods matter. Therefore what happens to

people living in these neighborhoods is of concern to policymakers. Since the majority of residents of poverty neighborhoods are children often in female-headed households, they are of particular concern. What happens to children residing in poverty neighborhoods is the subject of considerable debate. There is ample evidence, for example, that many of these children are not adequately nourished, are in need of more regular medical care, are not properly supervised, and are constantly exposed to drugs and criminal acts. But there is no consensus on what should be done to improve the quality of life for these children, let alone who should do it, and how it should be financed. At the same time, most urban dwellers believe that something needs to be done. Passage of the 1996 Welfare Reform Act may have a significant impact on many of these households as mothers are required to transfer from public assistance to work.

To a lesser extent, some of these concerns apply to the elderly who are often trapped in poverty neighborhoods. Even though municipalities, for the most part, have been conscientious in providing some services to the elderly (most notably transit, housing, and nutrition), environments in which these elderly reside, by most accounts, can be hazardous.

A second reason for concern about poverty neighborhoods revolves around the question of equity, particularly in the provision of public services. Poverty neighborhoods contain the oldest housing stock most in need of repair, the most deteriorated infrastructure, have the highest levels of toxic waste concentrations, and the least amount of open space, particularly in comparison with more affluent neighborhoods. Given these conditions, how should public resources be allocated to address these problems?

A third reason for concern is that poverty neighborhoods are believed to be the cause of a number of undesirable social conditions, high crime rates, family disintegration, incidences of major health problems including high infant mortality, tuberculosis, HIV/AIDS, alcoholism, and other antisocial behavior. These conditions if left unchecked could spread to other neighborhoods.

Finally, the concern with poverty neighborhoods centers around the widely held belief that these neighborhoods adversely impact other neighborhoods. Here the concern is often with crime and violence, the impact on property values, and how much of a tax drain poverty neighborhoods cause for other areas of the city. There is also the concern, as was evidenced in Los Angeles in 1992, that intolerable conditions can lead to civil unrest which has proven to be extremely costly (Orfield, 1997; Pastor, 1993).

Conclusion

After nearly four decades of research and efforts at policy reform and program intervention, one thing is abundantly clear – the number of persons in poverty is increasing and persons in poverty are becoming more and more concentrated. Between 1970 and 1990, the number of poor people in high-poverty neighborhoods nearly doubled, from 1.9 million to 3.7 million. This rate of growth exceeded the overall rate of increase in the total population in poverty neighborhoods during this same time period, in spite of the fact that during the 1980s the nation experienced good economic times. Most perplexing is the growing poverty rate among households where one or both adults are working. A robust economy might have provided jobs but not at wage levels that moved people out of poverty.

What is wrong? One might conclude that problems of poverty cannot be solved. Or one might suggest that those who are responsible for providing policy leadership on this issue simply have not found the right solution yet. More disturbing, however, is the thought that the vast number of Americans not in poverty simply do not care much about those who are.

Clearly, there is no simplistic solution to the question of poverty. Indeed this may be one of the problems. Politicians in their zeal to provide solutions respond to constituents or press accounts which usually focus on symptoms or sensational exposes. Researchers tend to focus on individual policy issues. What is needed, perhaps, is a more comprehensive policy approach which takes into account the structural sources of poverty, its multigenerational roots, and the link between individual neighborhoods and regions.

Abstract

The article discusses the concept of urban regeneration and summarizes the types of policies that make up urban regeneration as a public policy field. As urban regeneration policies are heavily context-dependent, the article uses the example of the United Kingdom to illustrate how urban regeneration policies have emerged and how they have been shaped by urban problems and by the dominant responses to them. The article concludes with a discussion of the current challenges to urban regeneration as both a concept and a policy field.

The Concept of Urban Regeneration

Defining what 'urban regeneration' is and what sort of interventions and policies that term encompasses is not straightforward. At the broadest level, it has been applied to any significant intervention improving rundown urban areas and is roughly synonymous with terms such as 'urban renewal,' 'urban revitalization,' or 'urban renaissance,' although there are subtle but not entirely negligible differences in meaning between them. 'Urban regeneration' has also become the most widely accepted translation in British English for expressions in other European languages designating similar interventions: stedelijke vernieuwing, renouvellement/renovation/regeneration urbaine, stadterneuerung, renovación urbana, etc.

The idea that urban areas need regenerating comes from a particular understanding of the causes of the problems of economic and social decline in industrial cities and of the appropriate policy responses to those problems. That understanding has at its core the proposition that the economic decline of a locality, with its attending social and environmental problems could be more effectively addressed as problems *of* that locality rather than as economic, social, or environmental problems that happened to take place in that locality. This notion began to take hold in the late 1960s in policy programs addressing social deprivation in inner-city areas (McCarthy, 2007) and was later to inform a wide variety of urban policy interventions, especially but not exclusively those concerned with improving the physical fabric of urban areas as a means to achieving wider policy goals. From its emergence as a distinct policy field in the 1970s to today, urban regeneration has come to signify that field of public policy that deals with the regrowth of economic activity, the restoration of social function or social inclusion, and the re-establishment of environmental quality in localities in which those elements have deteriorated (Couch and Fraser, 2003).

Urban regeneration policies seek to address the problems of a locality in all their multiple dimensions. A well-known British definition of urban regeneration emphasizes this interplay of physical, economic, and social dimensions of urban problems:

> "Comprehensive and integrated vision and action which leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental condition of an area that has been subject to change." (Roberts and Sykes, 2000: 17)

However, this multidimensionality of the concept of urban regeneration begs the question of what is that interaction, what are the causal nexuses it contains, and how they could be acted upon and in what direction. The notion of urban regeneration is based on the assumption that economic and social problems are not a-spatial, and the character of a location can determine the nature of those problems and compound them. Extensive areas of physical dereliction or inadequate physical infrastructure are likely to deter investment in a locality and make the spontaneous renovation of those areas far more difficult. The spatial concentration of socially disadvantaged groups might compound their problems by weakening their interactions with the rest of society and reinforcing patterns of social exclusion. It should be noted that some of these causal links have been assumed rather than demonstrated (see e.g., Cheshire, 2006).

Another element in the notion of urban regeneration is that the decline (physical, social, or economic) is of a structural nature and will not be reversed spontaneously as part of the normal process of change and adaptation that is part of the life of cities. In this case, change requires purposive action by the state through policy and direct intervention, as market forces are not sufficient to trigger and ensure adaptation or transformation. Another definition of urban regeneration puts it in this way:

> "The large scale process of adapting the built environment, with varying degrees of direction from the state." (Jones and Evans, 2013: 2)

The classical problems addressed by urban regeneration policies are widely acknowledged in the literature as those pertaining to the deterioration of the social, economic, and physical health of cities or parts of cities in the older industrialized economies of Europe and North America. These are in turn the result of structural changes in the last quarter of the twentieth century that saw the demise of traditional industries often leaving behind a weak economic basis, persistent problems of unemployment, and derelict sites; the suburbanization of the middle classes taking away from the city its tax base; the economic, physical, and environmental decline of central areas of cities with a deterioration of living conditions for its dwellers; and increasing and harder to bridge social inequality (Karadimitriou et al., 2013).

The problems addressed by urban regeneration are often described as examples of the 'wicked issues' of the policy literature. They are policy problems that seem intractable, persistent, and not amenable to simple solutions. Moreover, they are multifaceted; their consequences span over the areas of competence of many different government agencies; they are not amenable to solutions coming from one single powerful governmental actor and the involvement of actors beyond government; the timing for solutions to work tends to be much longer than conventional program horizons and electoral cycles.

There is also a scalar dimension to urban regeneration problems. Gripaios (2002) suggests that those problems could be classified roughly in two categories. The first comprises deteriorated areas within otherwise relatively prosperous cities, whose economy and population have persistently failed to benefit from the surrounding prosperity. The second encompasses those cities and areas of cities situated in regions with a depressed economy, which require interventions that go well beyond the locality and the city.

The multidimensionality of the problems addressed by urban regeneration interventions underpins the complexity of the objectives those interventions seek to achieve. These are marked by tensions, not just between different views of what a better city or city quarter might be, but also between different perceptions of the role of those different dimensions in bringing about the desired outcomes. The tensions between physical redevelopment and environmental improvement on the one hand, and social and economic benefits on the other are well documented (Turok, 1992; Swyngedow et al., 2002). Similarly, Butler and Hammet (2009) point out to a longstanding tension between encouraging economic competitiveness, with an emphasis on physical transformation, and encouraging social inclusion.

Consequently, over the nearly four decades in which urban regeneration policies have been pursued, their objectives have varied not only because of the varying nature of the problems associated with urban decline. The variation is also the result of different understandings of how multiple dimensions of regeneration relate to one another and how that relationship could be mobilized toward the desired aims, of different ideological perspectives from successive governments and varying balance of power of the potential beneficiaries and losers of regeneration policies. Across countries, different policy and institutional contexts have also shaped variations in urban regeneration policy objectives.

Current regeneration practice accepts that interventions need to go beyond physical redevelopment, and while this remains an important component, the main objectives tend to refer to stimulation of economic growth, together with the decrease of social inequality and the increase in community cohesion. More recently, environmental sustainability and climate change issues have gained considerable prominence as objectives of regeneration policy (Jones and Evans, 2013).

Those objectives are still quite broad and admit several different conceptions of how to attain them. As the public sector in most countries no longer has the capability or the appetite for large-scale direct intervention in the urban environment, achieving the economic goals of urban regeneration has come to depend largely on the performance of the property market. Stimulation of economic growth has often meant the provision of accommodation for businesses, or even just the employment generation and economic multiplier potential of the development industry (Turok, 1992). In both cases, the success of the intervention relies on altering the dynamics of local property markets. New buildings in renovated surroundings with a buoyant property market can change investor's perception of a locality and lead to more investment in the local economy. There is a well-explored connection between urban regeneration and city marketing, with physical changes in a locality (often through flagship developments) being used to boost the competitiveness of a location in attracting businesses, dwellers, and investment (Evans, 2005). In many cases, the re-integration of a derelict area into the mainstream property market itself has been seen in itself as a regeneration objective. The objective of stimulating the economy has also been translated into investment in urban infrastructure, especially as a way of increasing the competitiveness of urban regions (with e.g., improvement in public transport networks), although much of the multiplier effect of this investment also tends to depend on the stimulation of property markets. However, since the 1990s, the principle that regeneration should not be circumscribed to physical redevelopment has gained wide acceptance in theory, if not always in practice (Imrie et al., 2009).

Social equity objectives were originally restricted to housing and the replacement of inadequate dwellings. They were addressed mainly through the provision of more and/or better housing units, mostly by the state but subsequently with increasing degree of dependence on the workings of the housing market. More recently, this has come to include incentives to the creation of mixed income communities as a way of breaking the spatial concentration of poorer households, offer more opportunities for social mix, and thus lead to higher levels of social inclusion. Those objectives have also been frequently addressed through the provision of health, education, or leisure facilities, or indirectly, with the provision of employment that would result from the interventions described in the previous paragraphs.

The pursuit of economic competitiveness has gone beyond property redevelopment and has encompassed initiatives to foster the skills and competencies of local population through social capital building programs. In parallel, perception of the social objectives of regeneration as alleviating poverty and social deprivation has broadened to those of propagation of a cohesive society and a socially inclusive city (McCarthy, 2007; Imrie et al., 2009). These broader social objectives have been addressed through skills and training programs and social capital building initiatives, including communal asset ownership and community integration programs. The list also includes initiatives to reinforce community identity and change the perception of a locality among both its residents and outsiders removing stigma and injecting pride about the place (leading to stronger citizenship), and initiatives addressing the causes and consequences of crime and fear or crime.

Environmental sustainability objectives have now become an integral part of urban regeneration policy agendas as well. They have been pursued with varying degrees of effectiveness through decisions on location, development layout, density,

and use mix, infrastructure provision and building specifications, and indirectly through making possible and incentivizing more sustainable lifestyles (Flint and Raco, 2012).

However, although urban regeneration is often regarded as a comprehensive, holistic discipline, encompassing all the aspects described earlier, in practice it is rarely, if ever, truly comprehensive. The complexity of the problems it tries to address, together with the nature of the government machinery available to implement the policies and the balance of interests associated with each objective means that most urban regeneration practice is skewed toward either physical/environmental objectives, or economic growth and competitiveness or social inclusion. Tallon (2010) mentions a categorization of urban regeneration into 'people,' 'business,' and 'place'-based regeneration, reflecting that division. He also suggests a similar classification of economic, social/cultural, physical/environmental, plus a fourth category of 'governance,' encompassing those urban regeneration interventions whose main focus is on the engagement of local communities, the institutional framework for that engagement and the skills required for it.

Most noticeable has been the disjuncture between urban regeneration interventions with a physical and economic focus, and those with a neighborhood focus (or place/business and people focus, to use the terminology suggested earlier). In the UK, during the New Labour government (1997–2010), social inequality and community cohesion issues were increasingly separated from urban regeneration, and subsumed under the discourse and practice of *neighborhood renewal* (Jones and Evans, 2013). This term has been used to signify a much stronger focus on social issues than mainstream urban regeneration, with its increasing emphasis on economic development and competitiveness trough changes in the built environment. On the opposite end of the spectrum, in the first half of the 2000s, the term urban renaissance came to be understood as a form of urban regeneration that sought to address economic and social objectives through the promotion of high-quality urban and architectural design in towns and cities, in a spirit similar to US-based New Urbanism.

However, to understand how these different concepts of urban regeneration objectives and their associated policies and practices came about, we need to look at the context in which they emerged. The following section explores the history of urban regeneration in the UK as an example that illustrates the links between policy substance and context.

Urban Regeneration: Historical Evolution in the UK

As mentioned earlier, some of the core policy elements of what we now understand as urban regeneration began to appear in the 1960s as part of efforts to tackle problems of decline of cities in industrialized economies. In the UK, these polices were also part of the effort of *reconstruction*, not only of war-damaged urban areas, but also of the significant heritage of nineteenth century slum dwellings. In practice, these policies were very similar to those carried out at the time in the United States to counteract urban decline under the title of urban renewal. They involved extensive demolition of the inner cities and their replacement with modern buildings, mass housing, and road and transport infrastructure.

However, the demolish-and-rebuild solutions to problems of urban decline became gradually seen as inadequate or downright harmful to the communities they sought to help. Urban riots and unrest in the late 1960s demonstrated the inability of those interventions to deal with the complex social problems caused by de-industrialization, suburbanization, and the ghettoisation of poorer neighborhoods. In the UK, the first policies that would fit the contemporary understanding of urban regeneration appeared in the late 1960s and early 1970s (McCarthy, 2007). These were central government grants to local government for targeting urban areas with concentrated poverty and social needs.

As the decline in traditional urban industries and related unemployment, deterioration in living conditions, and physical dereliction continued throughout the 1970s and early 1980s, the economic dimension of the urban regeneration challenge grew in importance. That was now seen primarily as one of facilitating the restructuring of local economies and ensuring that they remained competitive, and that the significant investment embedded in existing physical and social infrastructure was not wasted. To the pro-market governments of the 1980s, that meant freeing up market forces and allowing them to trigger the regeneration of declining urban quarters. It also meant a reliance on property markets as the main instrument for the delivery the physical infrastructure for a regenerated local economy. Emblematic of this period are the large private-led but state-supported flagship projects such as Canary Wharf in London, which was meant to redefine the economic role of its location and create the wealth that would ultimately address problems of social need and deprivation. Whether or not they succeeded or were even capable of doing that is still a contentious point (see Swyngedow et al., 2002; Imrie et al., 2009).

Over time, some of these interventions did indeed succeed in reshaping the local economy, but their record in addressing the underlying social problems is far more questionable. Turok (1992) pointed out early on the limits of regeneration strategies based on an excessive reliance on property development and the weakness of the claims made in its favor. These strategies were always controversial, but in the end the property market crash of the late 1980s made their limitations clear. British urban regeneration policies in the 1990s went back to a previous model of area-based initiatives, spatially concentrated interventions with a broad set of aims including improvement in the housing stock, health and education facilities, training and employment, public realm, etc. However, differently from their 1960s and 1970s predecessors which had been awarded through need, these new area-based programs were secured through competition and required partnership arrangements between public sector bodies, private sector player, and increasingly voluntary and community sector organizations. In this, as pointed out by Leach and Percy-Smith (2001), urban regeneration reflected the increasing dominance of New Public Management approaches to government, with its emphasis in introducing private sector management practices into the running of the state.

Environmental sustainability objectives have been incorporated in urban regeneration agendas from the late 1990s and

in the following decade as part of concerted international efforts. This is manifest in the effort to reuse and regenerate previously developed land, or 'brownfields,' to increase urban densities and secure compact cities, and to better integrate regeneration projects and public transport networks. This period saw also a renewed emphasis on communities, expressed in efforts to address the use and income mix of neighborhoods, as well as their environmental quality. However, as suggested earlier, the emphasis on community and neighborhood regeneration meant also a tension with the economic development dimension of urban regeneration, which has remained the dominant component. In the UK as in other countries, the reconfiguration of the state toward a more reduced role led to a reliance on large property development projects with a significant component of private capital for the delivery of economic development objectives and the provision of urban infrastructure and all types of social and merit goods (Karadimitriou et al., 2013). Given the increasing role of culture and knowledge-related activities in the urban economies of industrialized countries, 'culture-led' regeneration became a common strategy, bolstered by the success of interventions in Bilbao and Barcelona, and also the Tate Modern in London and other examples elsewhere (Evans, 2005). Most of these interventions relied on the creation of flagship buildings with cultural functions as a way of changing the perception of a location at the national and often international level. The regenerative effects would come with increasing levels of inward investment, tourism (with all its multiplier effects), and a larger resident population, attracted by the new cultural facilities.

The financial crisis and economic downturn of 2008 slowed down the majority of regeneration interventions based on physical redevelopment not only in the UK but also in most of Europe, as property markets slumped. Paradoxically, austerity policies and cuts in public sector budgets have made more difficult for public sector bodies to meet urban regeneration objectives on their own. In the UK, the coalition government that came to power in 2010 has reacted to those challenges by concentrating government funding into economic regeneration, with grants, tax incentives, and aid to interventions that could create employment, boost the economy, and increase its competitiveness (Jones and Evans, 2013). On the other hand, under the banner of localism and 'the big society,' government has signaled its intention to devolve aspects of regeneration, and especially neighborhood regeneration to civil society, with incentives to the proliferation of community trusts, social enterprises, business improvement districts, local enterprise partnerships between businesses and local authorities, and similar mechanisms.

Finally, it is worth noticing that for most of its history hitherto, urban regeneration has been the concern of the industrialized economies of Europe and North America. However, in the last few years policies addressing urban decline and the need for urban redevelopment have been adopted in the recently industrialized economies of East Asia and elsewhere. South Korea has embarked in urban regeneration interventions to cope with the legacy of fast and unplanned urban growth (Shin, 2009), and more recently, China has started to look for solutions for the problems of urban degradation created by the phenomenally fast growth of its cities (He and Wu, 2007). These policies tend to follow the extensive demolition and rebuilding model of urban renewal, but there are also signs that these countries are rapidly becoming aware of the limitations of that model.

This very brief historical overview takes us to the current challenges facing urban regeneration and urban regeneration practices and policies.

The Challenges for Urban Regeneration

From the earlier discussion it becomes clear that urban regeneration is foremost an empirical policy field that tries to grapple with the complex connections between the built environment, the economy, and society at different scales and to intervene in processes and variables that are possibly too complex and often with unclear causation. However, the problems of urban decline are real and can dramatically affect the economic health and the social well-being of neighborhoods and put considerable pressure on governments. Urban regeneration practice has often tried to replicate 'what works,' even if it often cannot explain why it works or whether it would work in a different context. Time, however, has allowed lessons to be learned from the various regeneration interventions with their varying degrees of success. Nonetheless, some issues seem to persist and challenge regeneration practice as a whole. Some of the most important ones are discussed.

The first issue is the unresolved causal nexus between the built environment and the social and economic processes that take place in it. Current regeneration practice has gone a long way from simplistic assumptions of straightforward causality of the postwar years, but the relationship between physical improvement and social and economic outcomes is still poorly understood – if not in theory, certainly in regeneration practices. The existing evidence is inconclusive about whether regeneration programs based on physical restructuring and redevelopment have been the main determinant of long-term structural changes in the economy and social well-being of the areas where they have been applied, and whether change was in the intended direction and the benefits were received by those to whom they were intended (see Cheshire, 2006; Ball and Maginn, 2005; Webber et al., 2010). The persistence of such approaches in e.g., regeneration interventions associated with large sporting events, such as the 1992 Olympic Games in Barcelona Commonwealth Games in Manchester in 2002, the Sydney Olympics in 2000, or the recent 2012 London Olympics suggests a strong belief in the transformative powers of physical redevelopment. Clearly, the production of new buildings in previously derelict areas, given the right conditions, can attract an influx of occupiers and this in itself will change the economic profile of the target area as in Canary Wharf or Kings Cross in London. Similarly, the development of iconic buildings in the right location and circumstances (e.g., the Guggenheim Museum in Bilbao or the Tate Modern in London) can boost the local economy and help achieve broader social goals – although it might also cause displacement and gentrification and therefore direct the benefits from regeneration away from those to whom they had been targeted. However, the evidence is much less conclusive as regards more subtle and complex social objectives, such as the

creation of social mix through the provision of different types of housing or the creation of a sense of place through new and renovated public space (see Madanipour, 2005; Cheshire, 2006 for conflicting perspectives). There is also the question of whether the causal nexus, if and when it is present, is strong enough to counteract other social and economic determinants and produce all the outcomes that are expected in an urban regeneration intervention.

Urban regeneration is by nature place-focused and the second issue is that of the effectiveness of localized interventions in dealing with social and economic problems that have their roots in the structure of the regional or national economy and society, and might not be amenable to solutions at local level. This is the case e.g., with issues of unemployment, levels of skills in local population, and many of the factors that determine social exclusion. Even when these problems can be addressed to a modest extent at the level of a locality, the benefits produced by regeneration interventions are likely to leak out of the target area and community, as there are no spatial barriers preventing it. Similarly, incentives to improve the economic performance of a deprived area by e.g., providing tax incentives of new accommodation to incoming businesses might just lead to displacement of businesses from elsewhere if there are no changes in the regional economy (see Rhodes et al., 2005).

A third issue is the nature of the knowledge required for effective urban regeneration. Because of the complexity and multidimensionality of the problems urban regeneration has to deal with (see the earlier reference to the 'wicked issues'), no one single actor is likely to have all the necessary knowledge or the capacity to solve those problems on their own. The need for partnerships of various kinds between public sector bodies (especially local authorities), the private sector, voluntary sector organizations, and communities has been widely recognized in urban regeneration theory and practice. For reasons of efficiency as well as equity, the need for participation, partnership work, and co-production of policy outcomes has been reaffirmed in nearly all the urban regeneration literature (see Harding, 1998; Ball and Maginn, 2005). However, these different actors have different capacities for expressing their knowledge and integrating it in coherent set of objectives. Moreover, there is no reason to expect those objectives not to be conflictive with those of other actors, since they will derive different kinds of benefits from an urban regeneration intervention.

This takes us to the fourth issue. An enduring challenge in urban regeneration practice is to ensure that the appropriation of the benefits it creates serves the intended policy objectives and that those it was supposed to benefit actually do so. Urban regeneration implies a concerted effort to change the configuration and the social and economic dynamics of a place. This process almost always produces both winners and losers, but determining and controlling who they are is far from simple. Power structures in society, amounts of social capital accessible by different groups, distribution of property rights, mobilization capacity etc., will determine who captures what benefits (Cars et al., 2002). A common critique of urban regeneration through property development projects is that its benefits are more likely to be appropriated by development interests, local government, and incoming residents than by existing residents and businesses, whereas the disbenefits are more likely to fall to the latter (Imrie and Thomas, 1993; Swyngedow et al., 2002). It is a contentions point whether this is because converting regeneration benefits into property values, rents, local taxes, local GDP growth, and other monetizable outputs is more straightforward than converting them into less tangible and more uncertain social benefits for resident communities, as opposed to this being the result of an inherent structural bias in physical, property-based regeneration.

This is a weaker version of the argument that says that the inequalities in the appropriation of the benefits of urban regeneration are structural and intentional, and result from the dominance of neoliberal, business-dominated approaches to city management, and urban policy, which facilitates the appropriation of the city by large finance capital (Swyngedow et al., 2002; MacLaran, 2003). According to this argument, urban regeneration projects are essentially instruments to promote the re-valorization of land and buildings, gentrification, and the re-appropriation of parts of the city by the elites, the main beneficiaries of the economic impacts of such projects. Some of this argument draws on Harvey's (1985) formulation about the relationship between the built environment and capital accumulation, by which capital switches to the built environment when the profit rates in other productive spheres fall (see also Ball, 1986 for the critique). However, the fact that cities all over the world, under governments of different ideological profiles, insist on pursuing urban regeneration interventions with a significant component of land and property redevelopment would suggest that even with structural inequalities of voice and power, there is still the possibility of producing benefits that can reach disadvantaged groups. The key issues are therefore, how to control the appropriation of benefits and, in the unavoidable occurrence of losers, ensure that their concerns are also addressed. Once again, partnerships and other participatory mechanisms from policy definition to the long-term monitoring and management of outputs have been so far the answer.

The earlier discussion raised the question of how the public interest and, more specifically, the interests of deprived communities might be protected in urban regeneration interventions. For much of the history of urban policy in representative democracies, this was seen as the natural role of the state and the public sector. However, changes in the nature of local governance in mature democracies has led to an increase in collaborative forms of governing, with a less clear separation of roles between public and private sector and between government and civil society (Leach and Percy-Smith, 2001; Sullivan and Skelcher, 2002). The expression 'enabling state' has been used to describe a situation in which the state does not seek to deliver policy outcomes by itself, but rather enables others to do it. Urban regeneration is not an exception, and in many countries, regeneration policy objectives are predicated upon interventions in which the state is only one and not necessarily the dominant partner. The fifth issue is therefore how to secure accountability and representativeness in partnerships and other similar governance mechanisms, in a way that ensures that all those with a stake in the regeneration intervention are represented, but also that the conflicts that are unavoidable in that sort of

policy action do not prevent it from taking place (see Osborne, 2010).

A sixth issue relates to the nature of resources for urban regeneration. Traditionally, urban regeneration has relied on a mix of public funds and subsidies leveraging private investment. The more recent global economic downturn has affected the status-quo because of increasing pressure on public sector budgets. As a result, private and community resources have become essential for the delivery of policy outcomes. There has been an increasing reliance on private developer to deliver social goods (in the UK, this includes nonmarket housing) or in community organizations to secure long-term maintenance of amenities and social facilities. One of the main implications of this role of public, private, and community actors is that urban regeneration interventions require governance arrangements that ensure that the different types of uncertainties and risks faced by the actors are considered and reduced as far as possible (Karadimitriou et al., 2013). Urban regeneration is inherently uncertain and risky, and this includes financial and market risks for private partners, financial and political risks for public bodies, and risks to the welfare for the communities involved. Negotiating and arranging how risks and rewards are distributed is becoming therefore an important function of public sector bodies in multiactor regeneration interventions. In recent times, instruments such as land-readjustment, public land ownership, dedicated funding mechanisms, direct public investment, and tax mechanisms have been deployed with this purpose. The discussion around value capture – how the benefits and positive externalities caused by regeneration interventions can be captured and utilized to pay for public goods – is relevant in this regard (see Ingram and Hong, 2012). Mechanisms such as tax increment finance, planning obligations, and levies have been used with different degrees of success to convert what otherwise might be appropriated as private value into sources of funding the public goods urban regeneration should produce.

A final issue refers to the long-term sustainability of urban regeneration interventions, in the fullest sense of environmental, social, and economic sustainability. Under the influence of national and international directives, sustainability has become an essential objective in urban regeneration. The environmental dimension of sustainability has been addressed satisfactorily through considerations about the carbon footprint of renovated urban quarters, the energy efficiency of their buildings, and more broadly through public transport accessibility and the density and compactness of the urban form (Jones and Evans, 2013). However, this is not so with the other two dimensions of sustainability: social and economic sustainability are well defined in the literature, but their practical incorporation into policy is still problematic. A combination of urban design, participatory governance regimes, public transport investment, and strategic municipal planning and land acquisition has demonstrated the possibility of environmental and social sustainability in places such as Freiburg in Germany or Hammarby Sjöstad in Sweden. Nevertheless, generalizing such exceptional experiences remains difficult and the capacity of local level interventions to change structural processes that are regional, national, and often global remains a real issue.

Final Remarks

Urban regeneration has become the major component of urban policy in many countries. However, rather than a discipline firmly anchored in a solid body of theory, it is an empirical field of policy, trying to address the perceived problems of urban decline in all their complexity on the basis of interventions that have worked in similar circumstances and of views of causality that have not (yet) been disproved in the real world. As suggested earlier, its agenda reflects the prevailing understandings of urban problems, their causes, and remedies, themselves contested by the various interests affected by urban regeneration interventions. Nonetheless, those problems are real, and the need to reuse urban resources in a sustainable and socially inclusive way means that urban regeneration interventions will remain important tools for dealing with urban change. How well they will be able to produce the kinds of policy outcomes expected of them might well depend on how challenges such as those listed earlier are addressed and what sort of urban regeneration practice emerges from that.

Abstract

Space, place, and its connection to social relations make up the study of urban sociology. Urban sociology views cities as the spatial basis for the reproduction of inequality and as an integral part of the capitalist accumulation process. It relies on qualitative and quantitative methods to explain urban development, neighborhoods growth and decline, and their effects on people and their communities. Urban sociologists also rely more heavily on spatial methods to connect social relations to place. Contemporary research topics include global cities, globalizing urbanization, culture and neighborhood change, community and social networks, segregation, neighborhood change, concentrated poverty, and gentrification.

Introduction

Everyone the world over sooner or later becomes part of cities. What were rural places are rapidly merging with the metropolis as urban places continue to grow and conquer the hinterland. People either are moving to cities or finding themselves swept up in tidal forces of metropolitan development. Urbanization is becoming more and more a ubiquitous local, national, and global process. According to the United Nations (2012), sometime in early 2007, world urbanization crossed the 50% threshold, and for the first time in history, a majority of human beings lived in cities. By mid-century, the figure is projected to reach two-thirds. The future of humanity is clearly urban.

Urban sociology is a field designed to understand and make sense of these spatial trends and patterns for the people who live in cities. It is a field that explores city life from the vantage point of economic forces and global cities to a focus on the homeless person hanging out on the corner. It places cities and city life within the broad contours of mega theories, while also looking at how the lives of individuals are affected by the specific characteristics of places. Urban sociology's distinguishing feature is its focus on the role of space in people's lives. It looks at the connection between urban and metropolitan spatial organization and the social and economic situations of different social groups – people who vary by age, race, ethnicity, family type, country of origin, income, and socioeconomic status. Urban sociology embraces the diversity of social life and explores how it is played out across the physical contours of cities.

The focus on space is critical. Urban sociology is not the study of everything socially going on in cities, which ultimately, given the universality of the urban, would dominate the entire field of sociology. Urban sociology is about space – it is about land, development, housing, density, architecture, open space, distributions of land use, urban infrastructure, roads and transportation, neighborhood housing and population composition, and ultimately, location, location, location. Space, place, and its connection to people make up the study of urban sociology. Space literally and figuratively anchors the entire field.

Theory, Perspectives, and Schools of Thought

Urban sociology was born with the Industrial Revolution, the decline of feudalism, and the concomitant shift from a rural to urban society. Following Durkheim (1997 [1893]), these economic and spatial changes, according to Tönnies (1963 [1887]) and Simmel (1950 [1903]), altered fundamental social relationships and brought about society-wide transformations of increasing complexity. Moving from Gemeinshaft (community) to Gesellshaft (society) created an urban social order based on money and work, not family and faith – a condition both socially liberating and disconcerting (Simmel, 1950 [1903]). Economic structural changes and spatial reorganization required new mechanisms to foster social integration on the urban scene – a theoretical beginning that focused on the maintenance of social order and control. This quest for understanding this new urban order gave birth to the Chicago School and the field of urban ecology, which studied the forces underlying human spatial organization – the city.

A paradigm shift emerged with the recognition that cities were not the natural spatial expression of human organization. Instead, they represented the interests of a particular economic system (capitalism), were managed deliberately (through political policy), were used to enhance power and privilege (at the expense of others), and were the basis for the reproduction of inequality. These ideas heightened interest in a critical 'new' urban sociology that along with theory building viewed the field as a source for social change.

The Chicago School

The creation of a specific field called urban sociology took place in Chicago in the early years of the twentieth century, which focused exclusively on urban spatial formations and change and the social behaviors emerging within this new environment. With urbanization becoming a dominant trend, foreign immigrant's as well domestic migrants from rural America flocked to U.S. cities. Chicago was a prime destination. With the rapid and intense growth of the city, Chicago sociology observed the process of urbanization with wonder and awe. The people moving to cities spoke different languages and had

different customs, and world views, making the potential for chaos enormous. Yet order prevailed, both in terms of land use and behavior.

Sociologists turned to the established field of plant and animal ecology for guidance in understanding the prevailing order of human settlement patterns. Sociologists married ecological principles to the study of cities. Within this framework, the Chicago School of Urban Sociology was born. Leading the way was Robert Park, Ernest Burgess, Robert McKenzie, and others who solidified sociology's place as an American discipline focusing on the country's urban experience.

Urban ecology explained spatial dynamics as a complex web of competition between various groups for control over settlement space. Urban spatial organization was viewed as a natural process of environmental adaptation. Concepts including competition, dominance, adaptation, invasion, and succession explained urban spatial order and change.

The concentric zone introduced by Ernest Burgess (1967 [1925]) illustrated how housing and population organized themselves based on these principles. These principles of urban social-spatial organization preserved community by allowing different groups to select themselves into their own urban neighborhoods: Little Italy, Chinatown, and the like. Neither chaotic nor disorderly, the city exhibited a new urban order that the Chicago School sought to describe and explain.

The Chicago School based the creation and recreation of community on discovered processes of how neighborhoods change and conform to principles of segregation. The Chicago School explained segregation like other urban patterns as natural, inevitable, and uncontrollable (Park, 1936, 1967 [1925]; Burgess, 1967 [1925]; McKenzie, 1967 [1925]). As the mechanism through which community was produced and maintained, segregation was also a positive outcome, a process tied to what the Chicago School called the moral order of the city. The professed inevitability of the segregation of both people and land use conformed to prevailing attitudes toward race, class, and ethnicity as well as the economic fundamentals associated with early free market capitalism associated with cities.

Chicago School theorization of the city unilaterally portrayed urban spatial organization as the inevitable product of natural forces beyond the control of any group or individuals. The fundamental belief in the inevitability of urban order as well as the emphatic conviction that urban spatial patterns, particularly segregation, were positive developments eventually was called into question. Recognition that segregation by race represented discriminatory processes, not self-selection, was ultimately rendered illegal by civil rights legislation. Urban inequality, particularly by race, fostered a new look at those theories that appeared to provide sociological justification for an unfair spatial status quo. With the urban race riots of the 1960s, urban sociology's professed natural forces were revealed to be scholarly rationalizations for racism, discrimination, and the ghetto.

The New Urban Sociology, Urban Political Economy, and the Production of Space

The new urban sociology emerged as a deliberate critique of urban ecology. It incorporates the role of power and politics in the guise of the state organizing urban development in the interests of capitalism. The new urban sociology embraces and adapts ideas of Marxist geographers like David Harvey (1973) and Neil Smith (1979). Yet it asserts a role for human agency that often is missing from the more structural orientations of Marxist urbanism. It also retains urban ecology's focus on and belief in methods and research.

With a genesis in community power structure research pioneered by Floyd Hunter (1953), Harvey Molotch (1976) – and later in collaboration with John Logan (Logan and Molotch, 1987) – explicitly introduced the role of power and politics, not ecological forces, in shaping urban development. The city as a growth machine thesis argues that the shape and direction of urban development, particularly of downtowns, is the product of behind-the-scenes land-based activities by locally based coalitions of urban actors who stand to benefit from increased land and property values, land use intensity, and population expansion. These institutional actors include corporations, utilities, newspapers, universities, and unions as well as government who work collectively and concertedly because of shared interests.

With the power to orchestrate local political decision making, growth coalition activities are magnets for public underwriting and subsidy. Although these developments yield significant economic advantages to coalition members, their public payoffs appear minimal or even harmful. The growth machine agenda holds sway because of a well-articulated and disseminated ideology that maintains that growth is in the public interest despite ample evidence to the contrary. Popular acquiescence to growth machine projects is indicative of the hegemonic dominance of growth ideology. Contrary to urban ecology's insistence that cities are organized spatially according to processes that provide mutual benefits to all groups, the city as a growth machine stipulates that cities are a reflection of political, economic, and social manipulation and domination with clear winners and losers.

Marxist geography informed a Marxist urban sociology and it often is difficult to disentangle the disciplinary differences. David Harvey (1973) was the first to advocate for an urban political economy that explicitly links urban development to capitalism. Urban political economy focuses on how cities are involved in the circulation of capital and the reproduction of labor power. As part of capitalism's need to combat the falling rate of profit, cities also serve as the locale for collective consumption (Castells, 1977) – that is, the construction of publicly funded urban infrastructure that supports capitalist enterprises, subsidizes profits, and assists labor force reproduction. Cities are not simply places where capital is accumulated. Cities are an integral part of the capitalist accumulation process.

The physical expansion of cities reflects the use of cities to grow finance capital. Urban development and suburbanization are activities that require investment into the built environment. Urban development represents the shift of capital from manufactured commodities (the primary circuit of capital) to building homes and buildings (the secondary circuit of capital). Capital shifts between primary and secondary circuits reflect cycles of investment and disinvestment between these two circuits of capital (Harvey, 1973).

Urban decline and uneven development in the form of abandonment and neighborhood deterioration is not the absence of activity within these communities, but rather represent the active disinvestment of capital from communities (Smith, 1979). Reinvestment creates values while disinvestment removes it. Disinvestment is not simply a process in which buildings are neglected. Disinvestment devalues property as part of the process for later profitable revalorization. Urban political economy is the study of how capital accumulation actively develops and underdevelops neighborhoods, cities, and communities. The recognition of the crucial link between neighborhood vitality and housing finance led to many urban sociologists partnering with community-based organizations to fight neighborhood disinvestment (Shlay, 1989).

Urban political economy views cities as sites of production and capital accumulation (primary circuit of capital) and as places for consumption (the secondary circuit of capital) and for the reproduction of labor power (the generation of present and future labor market participants). Cities are an integral part of the reproduction of labor power by providing the physical environment in which labor power is recreated daily.

But Manuel Castells (1977) argued that cities are also sites for collective consumption i.e., publicly financed goods and services that are shared by urban residents. Collective consumption subsidizes the wage rate and increases capitalist profits therefore making city services a key factor in capitalist accumulation. In addition, different capacities of labor power are produced through the provision (or lack thereof) of education. Urban political economy implicates city services as mechanisms that create a stratified urban labor force. What is explicitly urban about collective consumption is that this occurs spatially.

Much of the original theoretical work defining urban political economy focuses on the production of space. Under capitalism, this is the initial and subsequent work at turning land into a commodity and using it as a fundamental component of capitalist accumulation and labor force reproduction. Henri Lefebvre (1991, 1996 [1968]), a French urban scholar and political activist, introduced the concept of production of space. The translation of his work was delayed, however, and so his direct contribution to the English-speaking world was mediated through the works of other urban Marxists (Harvey, 1973; Castells, 1977).

According to Lefebvre the ways in which space is produced is an integral part of the economic, political, and cultural dimensions of society. In *The Production of Space*, Lefebvre (1991) argued that capitalist forces produce abstract space, that is, homogenized spaces that are turned into exchange values. The abstraction of space is how urban development is used to create exchange values under capitalism despite the reality that space or spaces are unique locations that never can be abstract. Space cannot be fully abstract because space operates as distinct social places that are constructed by people through their daily activities and lived experiences. These social spaces of use values are areas where the culture of urban life thrives, often in direct conflict with the abstract space idea generated by capitalism. People use – that is, produce – space to live. Capitalism produces space to raise money. These uses are in conflict.

Abstract space, like abstract labor is the means for capitalist appropriation. Just as labor power can be abstracted and sold on the labor market, abstract space permits the exchange of land as a commodity. But the problem for capitalist domination is that labor and space are unique. For Lefebvre this conflict over social and abstract space is the decisive class struggle, leading him to reject the legitimacy of property rights and to argue that urban inhabitants by virtue of their residency have the right to participate in all land use decisions and to appropriate space. This is the 'right to the city' (Lefebvre, 1996 [1968]).

Securitization (the trading of finance raised off of the exchange value of land) has increased the abstraction of space to the point that space itself is no longer featured in financial transactions (Gotham, 2006). This ultimate abstraction of space is its financialization in which land is produced through the sale of financial instruments, that are, at least in theory, attached to the land (Gotham, 2006). Financialization represents land as a series of economic debts, obligations, and returns so that land in rural Idaho is rendered equivalent to land in New York City. The financialization of cities is an essential step for capitalist accumulation.

Urban theory's journey from urban ecology to urban political economy is one that continues to seek to explain urban development, neighborhood growth and decline, and their effects on people and their communities. It has moved its theoretical focus on explaining urban development away from ecological forces of self-selection. Urban political economy looks at the forces of capitalism – the commodification of land, the movement of capital into and out of the city's physical infrastructure, and the conflict for urban residents between property use and exchange values. Urban theory continues to look at large-scale forces that shape the urban scene.

But contemporary urban theory also emphasizes the role of agency – the decision-making power of growth coalitions is about the behind-the-scenes activities of urban actors with shared interests. The power of urban growth coalitions, however, appears to be diminishing with the tidal forces associated with financialization – forces directly tied to decision making within global financial markets.

Global Cities and Globalizing Urbanization

The major contemporary world force is globalization. Globalization involves the development of mobile global capital and a global economic market, the integration of a global division of labor, the rise of transnational corporations, and the diminished importance of nation-states. Theorizing about a global order and cities is the major frontier for urban sociological theory.

The focus of urban theory on globalization emphasizes a shift in how uneven development is addressed. Urban sociology initially addressed the uneven development within individual cities. With globalization, uneven development is a feature of the world. Urban development is expressed globally across an array of increasingly economically integrated cities.

Foreign direct investment in the global core, increased exchange between global financial markets, and the movement of industrial production from wealthier regions to poorer regions have corresponded with increased centralization of various firms and corporations that manage this increasingly complex and ever-growing system. As introduced by Saskia Sassen (1991) and others, global cities represent the 'command and control centers' of the globally integrated economy. Global cities, such as New York, London, and Tokyo, among others, are the locations of the major global stock exchanges, the headquarters of transnational corporations, and world trade and lending organizations. These organizations direct capital flows and investment and command institutional control of global resources and policy decisions, which make global cities the locus of power in an ever-globalizing world.

The concept of globalizing urbanization focuses on how global forces are treated on the ground by local urban institutions and actors. Globalizing urbanization addresses how local urban development reflects international trends associated with heightened immigration, intensifying racial and ethnicity segregation, the spatial polarization of rich and poor, the incorporation of market mechanisms into public planning, widespread gentrification, and the growing specter of fiscal crises at every level of government. Theorizing about globalizing urbanization emphasizes local decision making tied to forces of globalization. This is because globalizing cities are the frontiers for the implementation for global trends, such as neoliberalism, and are sites for local resistance and acquiescence (Brenner and Theodore, 2002).

Culture and Urban Places

Urban sociology's initial focus on culture and its connection to urban development began as a response that was seen as an overly deterministic model represented by urban ecology (Alihan, 1938). These early calls for assessing culture's role in urban spatial patterns argued that attitudes in the form of place-based attachments could counter the strongest economic forces.

Nonetheless, culture was largely ignored within urban sociology as scholars sought to distance themselves from culture-of-poverty arguments that allegedly blamed the victims. Culture as a central variable within urban sociology became more prominent as a feature of the consumption of housing, goods, and services within cities. Culture is now theorized as a critical accompaniment to the dynamics of both local and global forces associated with gentrification. Pioneer urban sociologist Sharon Zukin (1987) illustrated the demise of authenticity with the commodification of culture (and culture's corporate globalization) within gentrifying places. Culture is a market signal that attracts reinvestment and eventually global capital. Culture is a critical part of how urban space is commodified and transformed.

In a very different way, culture is also connected to spatially concentrated poverty (Wilson, 1987). Contemporary concentrated urban poverty is linked to a series of variables, including culture. But how culture is linked to the continuation of urban poverty is argued to be a complex phenomenon based on a combination of structural, spatial, and cultural variables. Those that connect culture to the spatial dynamics of poverty are careful to maintain that culture is not a determining factor of urban poverty but rather is an important feature of concentrated poverty (Wilson, 1996).

Methods in Urban Sociology

Urban sociology was born of a tradition rich in theory as well as method. Urban sociology's founders, the Chicago School, were data fiends embracing both quantitative and qualitative methods, including ethnographic research. The earliest urban sociologists plied their trade by mapping, counting, observing, and surveying. They pioneered participant observation, conducting some of the earliest studies using ethnographic methods.

The early urban sociologists were empirical. They cared about data, how they got it, and how they used it. The emphasis in urban sociology on using a wide range of rigorously applied methods continues. Although urban sociology, like most fields in sociology, periodically engages in pedantic methodological battles, it typically tends to value and support all types of empirical research, emphasizing the quality of the methods used.

This focus on careful empirical work gives urban sociologists standing within applied networks that rely on quality research for policy development, assessment, and application. In the applied research arena, the empirical work of urban sociology can rival the work of urban economics because sociologists, unlike most economists, know to collect primary data. One of the strengths of urban sociology, and typical of sociology generally, is a focus on research design.

An enduring strength of urban ethnographic research is exposing the 'hidden' worlds and clandestine cultures of urban inhabitants. But urban ethnography now studies the unusual as well as the seemingly mundane. Urban ethnography seeks to explore people's lifestyles, behaviors, decisions, and actions as well as the ways people frame their experiences and construct their identities. Urban ethnography captures a piece of urban life and connects these pieces to larger urban structures.

The standards for rigorous quantitative research in urban sociology are high. Urban sociologists rely heavily on primary and secondary data, are skilled in sampling and survey design, and have grown their skills at statistical analysis.

But being rigorous is not the sole domain of quantitative sociologists. Qualitative research in urban sociology also has become much more meticulous about method. The best urban researchers appear to understand the utility of both methods and many now heed the call for using multiple methods as part of a multifaceted research design (Small, 2009).

Urban sociologists also rely more heavily on spatial methods that permit them to connect social relations to place (Logan, 2012). The ideas behind the methods are less new than the ability to manipulate more data in a spatial way. More data sets contain geographic identifiers. Computerized mapping, geographic information system (GIS), and other software permit more sophisticated analysis.

Topics in Urban Sociology

Many make a fundamental mistake of thinking that the field of urban sociology is the generic study of people living in cities. This conflation stems in part from the media, which labels particular types of music as urban and stereotypes of what urban represents (e.g., minorities, criminals, poor). So it often is assumed that the studies of racial inequality, poverty, crime, and so on are *de facto* topics in urban sociology.

But studying people in cities is not urban sociology. Urban sociology is spatial in its orientation. If space is not a salient element in the research, it is not urban sociology. Place and space are the fundamental ingredients of urban sociology, a focus that links spatial location to social relations. This definition, therefore, provides some limits around the definition of topics within the field of urban sociology. Although many sociologists study race and many racial minorities live in cities, studying race is not urban sociology unless space and location are critical analytical variables.

This article highlights a few of most important topics in the field of urban sociology. These are community and social networks, segregation, neighborhood change, concentrated poverty, and gentrification.

Community and Social Networks

By definition, much of the discipline of sociology is about community – the underlying mechanisms that attach people together. Indeed, the construction, maintenance, and source of community were major topics for early urban sociologists who were concerned about the loss of social cohesion with the transition from rural to urban society.

Much of urban sociology is concerned with role of place-based communities in social and economic life. Studies of communities examine issues of power, class, gender, family composition, housing type and tenure, ethnic and racial diversity, crime and safety, and employment. Of particular importance are questions associated with the role of community in social mobility.

A central focus of contemporary community studies is the role of social networks (Wellman, 1999). Social networks, a key aspect of community, represent the basis for acquiring social capital. Social capital consists in part of relationships that may provide access to employment and other resources. A major question within urban sociology is whether the mixing of economic groups at the neighborhood level increases low-income families' access to social capital. For urban sociology, the question is whether mixed-income communities have positive effects on poor household's upward mobility. Linking mixed-income communities to economic mobility have been addressed most recently by sociologists involved in the Moving to Opportunity Experiment who have examined whether moving poor African-American families to middle-income white suburbs increases access to social capital by varying their social networks at the community level (Briggs et al., 2010).

Segregation

Segregation, like community, is a topic of long-standing interest within urban sociology. The Chicago School argued that social segregation was part of the underlying ecological structure that preserved community. Cities in early stages of urbanization were characterized by both racial and ethnic segregation – a period when ethnic differences between groups had great social significance. The city represented the amalgamation of difference. Segregation created village-like environments, thus permitting the social reconstruction of the village at the neighborhood level. Early urban sociologists viewed both racial and ethnic segregation in a positive light because they permitted socially similar people to make community together.

With the change in immigration policy, urban ethnic groups began the process of social homogenization that occurred with the reduced numbers of immigrants. Urban ethnic groups became white while the increased urbanization of African-American residents escalated. The segregation of newly white ethnic groups became less relevant to community construction and segregation by default was less prevalent. Yet the unabated racial segregation of African-Americans continued.

The civil rights movement and the urban riots of the 1960s propelled urban racial segregation into the public domain making the study of African-American segregation one of the most important research areas for urban sociology. Developing appropriate methods and measures for tracking racial segregation is a critical contribution of urban sociologists (Massey and Denton, 1993).

With the continuation of excessively high levels of racial segregation across most cities, urban sociologists also have investigated the underlying and not so mysterious causes of racial segregation. Urban sociologists have been at the forefront of researching housing market dynamics and segregative processes that create and maintain high levels of segregation (e.g., racial steering). In addition to the causes of racial segregation, urban sociologists also have been active in researching the consequences of segregation by examining neighborhood access and racial barriers to important income and wealth-generating resources across neighborhoods, such as housing finance (Squires, 1994; Shlay, 1988). This type of research has expanded to include examining the segregation of Hispanic and Asian households. Recent research suggests that segregation has decreased in some cities although the significance of this increase is debated (Logan and Stults, 2011; Glaeser and Vigdor, 2012).

With the Fair Housing Act, the Community Reinvestment Act, and other federal and local initiatives, urban sociologists play an important role in assessing the effectiveness of policy and the need for further intervention. Sociological research on discrimination in mortgage lending and homeowners insurance combined with effective political organizing and advocacy has helped propel the passage and increased the enforcement capabilities of legislation. Monitoring segregation and the effects of segregation continues to be crucial as communities work to stem the negative effects of race-based subprime and predatory lending and faulty underwriting.

Neighborhood Change

Urban sociology focuses on the dynamics of neighborhood change, specifically the precipitants of change, the process of change, the effects of change on households moving in and out,

and the effects of neighborhood change on the city and region as a whole. The Chicago School viewed neighborhood change as a process initiated by the 'invasion' of one type of different household (e.g., African-American) into a homogenous neighborhood (e.g., white). According to this perspective, this invasion served as a market signal that the neighborhood was transitional, leading eventually and seemingly inevitable from one type of neighborhood to another. In this way, urban ecology argued that invasion and succession were part of a normal set of mechanisms through which neighborhoods change.

Research now views the dynamics of neighborhood change much differently. Rather than viewing the movement of households as causing neighborhood change, urban sociology looks at the institutional mechanisms that precipitate particular types of changes. Neighborhoods are affected by the decision making within housing market institutions (e.g., real estate brokers, lenders, insurance agencies, etc.). What may appear to be a process governed by alleged principles of invasion and succession is actually a set of changes fueled by decisions made by housing market actors.

The focus on how housing market institutions affect neighborhoods is important largely because these decisions can be changed. The dynamics of racial change, abandonment, gentrification, and the like are not driven by housing preferences independent of the housing market context that is shaped by institutional actors such as lenders. Understanding the role of institutions in affecting neighborhood change is vital to promoting fair housing and increasing housing opportunities across the racial, ethnic, and class spectrum.

Concentrated Poverty

Concentrated poverty describes neighborhoods of largely extremely poor people devoid of income diversity. Neighborhoods characterized by concentrated poverty are believed to be socially and economically set apart from others because of their combined social and spatial isolation. Concentrated poverty is believed to have effects beyond the sheer numbers of extremely poor people. Rather, people living in neighborhoods with concentrated poverty maintain destructive and overtly negative lifestyles and behaviors that prolong their impoverishment. The combination of spatial and social variables in the form of concentrated poverty has fostered a spatial orientation to problems of poverty (Wilson, 1987).

Deconcentrating poverty has become part of a set of policy tools to alter the life circumstances of extremely poor families. As part of Hope VI, destroying large and dense public housing developments was also a form of deconcentrating poverty. Similarly Hope VI developments of mixed-income housing have sought to deconcentrate poverty. The Moving to Opportunity federal initiative that moved poor families out of public housing and into white suburban communities is yet another attempt at poverty deconcentration.

Whether deconcentrating poverty is effective in promoting more opportunities and economic advancement for poor families is not entirely clear. Much of what appears to be a form of poverty deconcentration may really be the residential displacement of poor families. Moreover, concentrated poverty continues to be a feature of most American cities, making it an important area for continued research on the spatial aspects of urban poverty.

Gentrification

Gentrification is a type of neighborhood change. A neighborhood undergoing gentrification is typically a community of low and moderate income with old but architecturally significant housing to which middle- and upper-income households are moving. The initiation of gentrification often occurs with the initial move in of artists looking for inexpensive homes and studios. A neighborhood that is fully gentrified contains predominately higher income families who live in housing whose values have soared and that have undergone extensive renovations.

In its initial phase in the early 1980s, gentrification was thought to be driven by a 'back to the city' movement. Later, scholars recognized that gentrification was driven by the reinvestment of capital in these depressed communities (Smith, 1979). The idea was that property values were so low that windfall profits were likely in the wake of gentrification. Gentrification represents property revalorization based on changing flows of capital. Yet these gentrified communities were not widespread and aptly were characterized as 'islands of renewal in seas of decay' (Berry, 1985).

In major cities, gentrification has become more widespread and is now considered a worldwide phenomenon. In many ways, the scope of what may be called gentrification has gone far beyond the speculative flipping of a few old properties. Gentrification has been suggested to be a 'global urban strategy' (Smith, 2002). This newer form of gentrification is believed to be fueled by state subsidies of transportation and other forms of infrastructure that creates large incentives for private sector investment. In this context, gentrification may no longer be a characteristic of how particular neighborhoods change but may represent large change in the city as a whole.

Urban Sociology and Policy

The genesis of urban sociology occurred during the formative years of American urbanization – a time of dramatic change in people's living conditions and a physical crush of social and economic difference amid new rules of behavior. The Chicago School was attracted by the mystery and magic of urbanization. They delved into this new spatial arrangement to gain an understanding of these dramatic changes and to do good. They saw a role for urban sociology to make cities better places. Of course, they embodied the racist, classist, and elitist ideologies of the period in which they lived and created. But within that ideological context, they sought to apply sociology to steer away from bad outcomes and to achieve what they believed was the moral order of the city.

Contemporary urban sociology is less self righteous about city life and less holistic in its approach to urban problems. While theoretical work on cities takes into account massive forces of capitalism and global inequality, the empirical work of urban sociology is more focused and compartmentalized. In the tradition of the Chicago School, many urban sociologists continue with the goal of doing good. But their good works are

focused on very specific problems. Urban sociology purports to do some good and to inform public policy. But the field has no vision of what constitutes a good city and its efforts within the policy field are piece meal.

Nonetheless, urban sociology may claim credit for working on a large number of issues in urban policy. These issues include fair housing, redlining, mortgage discrimination, affordable housing, low-income homeownership, exclusionary zoning, housing abandonment, homelessness, welfare dependency, unemployment, concentrated poverty, gentrification, downtown development, uneven development, neighborhood decay, gender discrimination, and tenants rights.

The Future of Urban Sociology

Although urban policy may not be the stuff of presidential elections and federal political maneuvering, the centrality of cities and place continues. Indeed, urban scholars suggest that matters associated with place will intensify with the heightened metropolitan inequality that is becoming more visible spatially. Urban sociology's future will continue to be concerned with the forces that shape cities and the quality of urban life. These topics will include the following:

- Gentrification and the intensifying capture of central city neighborhoods by elite groups
- Immigration and the flow of unparalleled diversity and difference moving to cities around the globe
- Globalization of housing finance and its effects on housing and neighborhoods
- The role of neighborhoods and the underpinnings of neighborhood effects
- Changing growth politics and power dynamics associated with place
- The role of racial segregation in maintaining intransigent urban poverty
- The impediments to racial and ethnic spatial assimilation
- The decentralization and suburbanization of poverty
- The growth of urban inequality and social movements
- Obstacles and possibilities for environmentally sustainable cities

In the midst of the ongoing disinvestment and reinvestment fueled by global capitalism, urban sociology will tackle thorny issues around the predictable cycles of uneven development. In the meantime, cities will remain places of magic, mystery, and misery.

Urban Sprawl

Robert Bruegmann, University of Illinois at Chicago, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term *urban sprawl* has been used to describe low-density automobile-oriented settlement patterns with little comprehensive public planning. Opponents of this kind of settlement pattern claim that it is economically inefficient, socially inequitable, environmentally damaging, and aesthetically ugly. They have called for more planning, growth restrictions, growth boundaries, greenbelts, open space conservation, environmental laws, historic preservation, and other mechanisms to promote many of the compact, transit-oriented cities. Other observers suggest that the problems with sprawl have been overrated and the efforts to stop it are likely to be ineffectual or to backfire.

Urban sprawl is an imprecise, usually derogatory, term used most commonly in affluent countries of the English-speaking world to describe certain kinds of low-density automobile-oriented urban settlement patterns with little comprehensive public planning. Opponents of this kind of settlement pattern claim that it is economically inefficient, socially inequitable, environmentally damaging, and aesthetically ugly. To halt sprawl, reformers have called for more highly planned, compact, transit-oriented cities, growth restrictions, growth boundaries, greenbelts, open space conservation, and historic preservation. Although the term has been used by some planners and other experts for most of the last century, it became a major public concern in most countries only in the economic boom period of the last years of the twentieth century. At the same time, however, it has become clear that even some of the most basic assumptions about sprawl, its causes and effects, are in dispute.

History of the Term

The kinds of condition described by the term *sprawl* have been visible in urban areas for centuries. Already by the beginning of the modern era, for example, there were complaints about settlements straggling out from large European cities like London and Paris, and there were attempts to curtail this growth. These complaints seem to have coalesced in Britain following World War I when the term sprawl as a noun with something like its current meaning came into general usage (Bruegmann, 1996, 2000, 2005). One of the most conspicuous opponents of sprawl was Thomas Sharp, the planner, who issued vitriolic attacks on 'semi-suburbia,' 'ribbon developments' along roads leading out of town, and suburban villas marring the countryside (Sharp, 1932). His cause was taken up by groups such as the Council for the Preservation of Rural England with its constituency of architects, planners, large landowners, and members of Britain's artistic and intellectual elite. Several bills passed in the 1930s aimed at restricting ribbon development and creating greenbelts around cities (Hall, 1988).

The original criticisms of sprawl were primarily based on aesthetic and symbolic considerations. Critics derided it as ugly and as causing a blurring of the traditional distinctions between the city and the countryside. Complaints about sprawl have continued to accompany every era of major prosperity, but their content has changed considerably depending on the time and place. Immediately after World War II, for example, sprawl became less of an issue in Britain because it, like many continental European countries, had been exhausted economically by the war. Furthermore, in Britain and northern Europe, governments increasingly adopted stringent controls on peripheral development, so it was widely believed that it was no longer a problem. In the United States, on the other hand, the prosperity of the postwar years without any strong growth control planning led to a tremendous suburban boom. Consequently, the most conspicuous negative reactions to sprawl in the postwar years came from the United States. Although aesthetic objections still loomed large, the particular circumstances of American suburbia led to increased objections on social grounds.

The most conspicuous use of the term *sprawl* in the postwar decades came from William H. Whyte, who organized a conference for *Fortune* magazine on the subject and then published a jeremiad against sprawl in *The Exploding Metropolis*, a book that he edited (Whyte, 1958). For Whyte, as for Jane Jacobs and many other American critics of suburbia, Los Angeles became the prime example of all of the evils of sprawl.

Anti-sprawl sentiments subsided somewhat during the economic downturn of the 1970s when development slowed significantly. During the last decades of the twentieth century, however, development boomed once across much of the developed world and even more so in some of the developing world. Concerns about sprawl became widespread, particularly because of important new arguments against it on environmental grounds.

As the various strands of the sprawl argument emerged in recent years, the term has become more common, but it never acquired a clear definition. By the early twenty-first century, it could mean many different things. Almost everyone agreed that it referred to low-density development, but there has been a major debate in academia about how to measure sprawl and to understand its dynamics (Wolman et al., 2005).

For example, sprawl commonly refers to settlement that is scattered, discontinuous, leapfrog, or ribbon, but as many observers have pointed out, with additional development the low-density discontinuous settlement of one era often becomes the compact, and high-density settlement of the next

(Lessinger, 1962). Sprawl also refers to automobile-dependent development or development with poor access from home to work or to public open spaces, but many other observers have pointed out that, as cities have become wealthier, they have almost inevitably seen more automobile usage and, despite the problems they create, automobiles have greatly increased mobility for a larger and larger part of the urban population.

For many years scholars outside the English-speaking world tended to avoid the term. Labels like *città diffusa* in Italian or *ciudad dispersa* in Spanish were coined to talk about entire urban regions in continental Europe. Variations of the term *peri-urbain* or *rurbain* were used to discuss parts of the urban realm that in the English-speaking world were called suburbs and exurbs. In Germany, Thomas Sieverts introduced the concept of *Zwischenstadt* to designate the interstices within and between cities. In Japan, the term *supurôru* was coined to designate what English commentators called sprawl, although the target was more haphazard growth and lack of adequate infrastructure than any specific desire to make development more compact (Hebbert, 1994; Sorenson and Ikata, 2009; Sieverts, 1997; Monclus, 1998; Nivola, 1999; European Union, 1990; Brake et al, 2001; Whitehand and Carr, 2001; Richardson and Bae, 2004; European Environmental Agency, 2006; Phelps, 2006; Crouch et al, 2007; Hall and Pain, 2009).

Despite the confusion over definitions, by the turn of the twenty-first century the term *sprawl* had gained acceptance not just in the affluent West but also in many other places around the world. Important coalitions to fight scattered, low-density, automobile-oriented growth at the periphery of urban areas have sprung up in virtually every place where growth has been significant (Sudjic, 1992; Bogart, 2006). In the United States, the term *smart growth* became important in the 1990s to designate efforts to combat sprawl. In England, Canada, and Australia, the *compact city* tended to be the term used to refer to the opposite of sprawl. Within the last two decades throughout much of the world, sprawl has been seen as contrasting with sustainable development, another term with a large literature and extremely divergent definitions (Jenks et al., 1996).

Objections to Sprawl

Objections to sprawl raised by reformers have shifted significantly over the years according to the times and conditions in various parts of the world. They can, however, be classified under four major headings that range from the apparently quite objective to the obviously very subjective. These categories might be designated economic efficiency, social equity, environmental sustainability, and aesthetic value.

Efficiency Concerns

Although the earliest and most constant objections to sprawl have been aesthetic, the debate about public policy to curb sprawl has primarily been conducted in more objective terms. One of the most extensive segments of this literature has targeted the alleged inefficiencies of sprawl. The most important early summary of these issues in the United States in the postwar decades appeared in the Costs of Sprawl report issued by the Real Estate Research Corporation (1974). Using hypothetical models of various kinds of development, this report concluded that master-planned communities at fairly high densities were more efficient in terms of private development costs and public infrastructure costs than what they called unplanned communities at low densities. This report was attacked immediately on several fronts. Before the report had appeared, several researchers had noted that what appeared to be scattered, low-density development was often only the first stage of urban growth and that the undeveloped land might eventually invite even higher densities than if the settlement had been built all at one time (Lessinger, 1962). Another attack on the conclusions in the report came from reviewers who stated that the apparent savings actually were primarily due to the failure of the report to hold conditions constant in the various models (Altshuler, 1977; Windsor, 1979). Other researchers suggested that master planning in practice, as opposed to the hypothetical models used by the Real Estate Research Corporation, not only did not always yield the savings that should have been expected but often turned out to be more expensive and risky because of high upfront costs (Peiser, 1984). The supposed efficiencies of high density were also disputed (Ladd, 1992). More recently, a new report on the costs of sprawl has tried to respond to these challenges (Burchell et al., 1998). According to the authors of this report, the dire predictions of previous researchers have not materialized but, they opined, the higher costs of low-density settlement, particularly road and other infrastructure costs, would soon become intolerable.

Social Concerns

The second charge against sprawl, that it exacerbates economic and social inequities, has been more common in the United States than elsewhere because for many years the suburbs were substantially wealthier and housed fewer minorities than the central cities. This was particularly true after the unrest in American cities in the 1960s when many affluent families moved from the central city to the far suburbs. According to the view of many anti-sprawl advocates, this move in the population was motivated in large part by racism, and the low-density suburbs, were an attempt by middle-class citizens to distance themselves from social problems in the city. Other observers, however, have noted that sprawl has occurred in much the same way in metropolitan areas with few minorities as in areas with large minority populations, suggesting that race, while important, may not have been a decisive factor. They also note that American suburban areas have always been more diverse than they were often portrayed in the media and that in recent years they have become increasingly so (Harris and Larkham, 1999).

Another strand of thought has involved the treatment of central cities and suburban areas by governmental bodies. Many opponents of sprawl believe that sprawl in the United States was not inevitable or even a freely made choice by most of the population. Instead, they posited, it was a condition that was induced artificially by massive federal subsides in favor of homeownership, notably homeowner insurance guarantees, mortgage interest deductions, and federal funding for the massive postwar highway-building program. This is disputed by those who point out that many of these policies could have

benefited central cities at least as much as suburbs if there had been demand for city living and that massive decentralization has occurred throughout the world in places where these policies were not in place. Whatever the causes, as affluent citizens moved out of the central city, this move unquestionably did tend to maroon many poor and minority families who were unable or unwilling to move. At the same time, it tended to deplete the tax base of the older municipalities as they lost sales taxes and property taxes to outlying municipalities.

Another charge against sprawl in the United States has been a belief that sprawl leads inevitably to impoverished social relationships and less robust communities. Antagonism to sprawl on social grounds has often been bound up with attacks on suburbs generally. A group of famous sociological studies in the postwar years, for example, the work of Daniel Riesman, portrayed American suburbs as alienating, soulless places. This view has, however, been rebutted by other sociologists, for example, Herbert Gans (Riesman, 1950; Whyte, 1958; Gans, 1967).

Another target of criticism aimed primarily at the suburbs has been the privatization of public spaces, for example, the rise of gated communities and the decline of Main Street shopping centers in favor of suburban shopping malls (Sorkin, 1992). For others, however, what is important in social relationships and community has not changed. Only the outward forms of it have changed. In this perspective, the public areas of the mall actually do function much like the streets of city centers, and gated communities are no different in kind than condominium buildings in central cities with their doormen and security systems.

Environmental Concerns

Environmental concerns started to play an increasing role in anti-sprawl polemics following the ecological activism of the late 1960s. Indictments of sprawl on environmental grounds became common in the 1990s following a wave of interest in the idea of sustainability. According to this line of thought, low-density settlement inevitably leads to excessive energy usage, particularly gasoline for automobiles (Newman and Kenworthy, 1989). This in turn leads to the depletion of resources and to increased pollution and greenhouse gas emissions. Low-density settlement also leads to the loss of farmland, most seriously prime farmland near urban areas, to the loss of forests, wetlands, and other open lands, and to the loss of animal habitat. Sustainable cities, according to opponents of sprawl, will be higher density with a greater use of transit and a better balance of housing and jobs and less encroachment on agricultural and open land (Jenks et al., 1996; Brotchie et al., 1995).

Sprawl opponents particularly decry cities in the United States, because they use more energy than their counterparts in Europe and much more energy than cities in poorer parts of the world. For many environmentalists, this constitutes a fundamental human challenge that can only be solved by stringent conservation measures and replanning cities to be more compact and energy-efficient. Other scholars have noted a history of dire warnings about looming energy shortages and ecological disaster, none of which has come to pass, and have suggested that there are much more efficient and inexpensive ways to cut down on energy use and greenhouse gas emission than remaking the urban environment. In any case, they claim, no amount of replanning and conservation will by itself be able to compensate for the enormous growth in energy use that will almost inevitably occur as the poorest nations of the world are able to gain for themselves middle-class lifestyles. Only major advances in technology are likely to solve the problem.

Perhaps the most contentious area involving both energy consumption and environment remains the use of the private automobile. Sprawl reformers are almost unanimous in the belief that private automobile usage must be curtailed and public transportation greatly strengthened to reduce both congestion and pollution. However, the idea that it will be possible to counter the rise in automobile ownership and per capita vehicle miles traveled, which is a feature of virtually every city in the world as it has become more affluent, or to counter the long-term drop in the proportion of citizens riding public transportation, which has also been true in virtually all of these places, is, according to some observers, both unlikely and undesirable (Gordon and Richardson, 1997; Staley, 1999). These observers also point out that automobiles have become so much more energy-efficient that they often use less energy and emit fewer greenhouse gases per vehicle mile traveled than buses.

Another emotional part of the debate about sprawl has concerned the loss of farmland. According to many anti-sprawl reformers, cropland, particularly prime cropland, is an irreplaceable asset that is being fast eroded by urban expansion. Those who take an opposing view counter that saving farmland is not that urgent because, due to new agricultural methods, farmland productivity has soared over the last several decades, even as cropland has been lost to urbanization. In much of the affluent world, they point out, government subsidies have led to a great deal of excess production and surpluses that are often then sold to some of the poorest countries in the world at very low prices, badly undercutting agricultural production in these places.

Aesthetic Concerns

The final complaint about sprawl, that it is ugly, has inspired the most constant and abundant literature throughout the years. The sprawling city has been said to be unplanned, chaotic, monotonous, neither urban nor rural, but a combination of the worst aspects of each. One of the chief problems with this kind of judgment, of course, is that it is inherently subjective. Various individuals and groups differ widely in their aesthetic sensibilities, and even within a single individual or group, responses can change dramatically over the years. It has also been conspicuous, from the interwar complaints of British landowners down to the beginning of the twenty-first century, that there are class-bound aesthetic interests at work in this kind of critique.

Proposed Remedies for Sprawl

The most obvious and dramatic remedy for sprawl would be to stop new development outside existing urban areas altogether. This could be done by outright governmental prohibitions or

by limiting the development of necessary infrastructure, notably roads, water delivery systems, and wastewater treatment facilities. Although this has worked in Russia and China and other places with highly authoritarian regimes and even in places like Singapore and Hong Kong, it has been very difficult in the democratic countries of the affluent West. Instead governments in these countries have tried to channel growth.

Channeling or Managing Growth

One of the earliest and most important attempts to manage growth was the greenbelt system instituted around British cities, notably around London. In this system, which was made possible by a nationalization of all development rights in Britain after World War II, a growth boundary was established around British cities marking the inner edge of a greenbelt in which development was forbidden. Any additional growth that could not be accommodated within the greenbelt was to be confined to existing towns and villages beyond the greenbelt, and to newly established 'new towns (Abercrombie, 1945).' This system, which borrowed many features from Ebenezer Howard and his garden city concepts, did stop growth at the edge of the greenbelt. It was not nearly as successful in containing growth beyond the belt. In fact, growth beyond the greenbelt eventually scattered across much of southeast England. Moreover, by restricting the land available for new development adjacent to the already built-up area, it very likely raised land prices considerably, making it more difficult for people of modest means to afford housing, and perhaps driving them further out than would have been the case without the restrictions (Hall et al., 1973).

However, flawed it might have been in practice, the greenbelt model has been very attractive to planners. A similar kind of greenbelt, together with a set of policies encouraging compaction and public transportation, has been put in place around cities from Toronto to Seoul, South Korea (Troy, 1996). One of the most carefully examined cases has been the one in the state of Oregon since the 1970s. The experience of Portland, which has been America's most conspicuous exemplar of anti-sprawl planning, has been watched closely and debated hotly (Abbott et al., 1994; Mildner et al., 1996).

In other cities, other schemes were devised to channel growth. Immediately after World War II, Copenhagen experimented with a finger plan in which corridors of growth would alternate with green wedges. This kind of system was widely emulated. In other places, planners advocated widely spaced new centers to channel growth. Around Paris, for example, new development was to be channeled into specific growth axes organized around transportation lines and large new towns like St. Quentin en Yvelines and Marne-la-Vallee. One virtue of these finger or corridor proposals was that they mirrored the way development had occurred historically along rail lines. In practice, however, it proved increasingly difficult to enforce these corridors as expanded car ownership freed citizens from the constraints of remaining close to transit stops.

In the United States, in the wake of the postwar boom period, the slow growth and no growth movements became prominent in the 1960s and 1970s as a way to slow change, particularly at the urban edge. In most cases, growth was slowed in a given area, but subsequent research has suggested that the growth often merely migrated to adjacent, less regulated communities as the constraint on supply put sharp upward pressure on prices in the regulated areas (Porter, 1997; Garvin, 1996). By the 1990s, there was an increased push to reign in sprawl by managing infrastructure development. Concurrency rules dictate that adequate roadway, water, and sewer capacity be in place before development is permitted.

Open Space Conservation

Another measure sometimes counted as an anti-sprawl technique involves the creation of permanent open space. This can be done by legislative fiat, by the purchase of land, by the purchase of development rights, or by some combination of these mechanisms. Of course, in itself, these measures don't stop sprawl. In fact, absent other controls, it is possible that they simply push development out further than it would otherwise go. One could draw this conclusion from the London greenbelt or from San Francisco where a great many local initiatives to save open space and stop development have pushed settlement out into California's Central Valley.

A dramatic example of the use of open space to guide development can be seen in Hong Kong where British planning methods were adopted with even more rigor than they could be in Britain. Outside of central Hong Kong, authorities set aside a large percentage of the territory as country parks. All new development had to be contained in new towns built at very high densities above railroad stations. The scheme has been carried out largely as planned. The new towns have densities as high as central Hong Kong, making this the only affluent city in the world with densities equal to those of large nineteenth-century cities. It has meant that Hong Kong has been able to provide extremely efficient public transportation. On the other hand, it appears to have driven up land and house prices very dramatically.

Governmental Structures and Incentives

Other techniques for curbing low-density settlement and promoting high-density growth involve governmental policies and structure. In the United States, many sprawl reformers believe that the American tradition of deciding land-use policies at the local level, combined in many cities with a fragmented system of municipal government, has led to a lack of coherence in planning and created major incentives for municipalities to encourage sprawl (Gottdiener, 1977). The remedy proposed by many reformers was to institute metropolitan-wide governments with strong planning responsibilities, or to push responsibility for planning up to the state or federal level, so that local competition for tax dollars would be less important in planning decisions. Moreover, tax revenues would be shared more evenly, making it difficult to move to avoid taxes and allowing the possibility of a more equitable distribution of income for schools and other public services (Orfield, 1997). Among the most important metropolitan governments in North America are those of Portland, Minneapolis-St. Paul, and Toronto. States that have initiated strong growth management laws include Hawaii, Oregon, Florida, and New Jersey. Whether or not these policies will have any

substantial effect in stopping the outward decentralization of people and jobs in the long run is still unknown, and in recent years a number of these policies have been overturned or scaled back.

Another area targeted by reformers involves tax policies and other governmental fiscal measures. According to these reformers, sprawl in the United States was subsidized by federal mortgage insurance policies and mortgage interest deduction on the income tax. Low-density settlement was also subsidized by heavy federal subsidies for roads and the lack of subsidies at the same scale for public transportation. Many American reformers would like to see the end of the federal mortgage interest deductions, the imposition of heavy taxes on gasoline and vehicles to offset the damage they do to the environment, and much greater funding for transit (Downs, 1994). Other observers question whether any program to increase fees on private transportation would, given the apparently inexorable trend toward low density, actually lead to enough transit use to offset the undoubted increases in highway congestion and pollution (Gordon and Richardson, 1997). The prospect of alternative energy for private vehicles and the possibility of new forms of hybrid transportation systems, such as private rapid transit, very small, and driverless vehicles, might well alter all perspectives.

Design Solutions

A final set of recommendations to deal with sprawl has been made at the level of urban design. Throughout the affluent world there have been advocates for undoing what they consider to be the damage wrought by Modernist architecture and town planning and a corresponding segregating out of land uses into single-purpose districts. An important example in the United States has been the movement loosely called the New Urbanism which involves an attempt to create higher density traditional settlements with a mix of uses to promote community and transit use (Katz, 1994; Duany et al., 2000). A related movement is the push to create transit-oriented design in which high-density mixed-use developments are planned near transit stations. The new developments around some Washington DC Metro stations are considered a good example. It is again too early to judge the success of these efforts. On the one hand, New Urbanists have created a large number of new communities, and their form-based zoning which regulates building envelopes as an alternative to typical American zoning by land use has been adopted by a large number of local jurisdictions. However, it is not clear whether the techniques of Smart Growth have started to change mainstream patterns of urban development in any fundamental way.

The Sprawl Debate

Beyond the question of problems supposedly created by sprawl, or the efficacy of any particular remedy, is a larger set of questions about some of the most basic assumptions about sprawl itself, whether it is recent or has been evident for a long time, whether it is accelerating or is actually declining. There has actually been very little research on many of these questions. However, there does seem to be some evidence that in the United States, where the debate at the end of the twentieth century was hottest, decentralization and sprawl might actually have peaked in the period between the 1920s and the end of the postwar decades, meaning that the ratio of land consumption to population growth was greater during these periods than anytime since. Certainly, residential lot sizes at the suburban edge have been falling, and an increasing number of American urbanized areas are growing in density. Most strikingly, the Los Angeles region, still in much of popular opinion the prime exemplar of sprawl, has gotten so much denser over the last half century that it is currently the densest urbanized region in the United States and denser than a number of European urban areas (Demographia.com; Bruegmann, 2005).

There is also a fundamental question about whether the denser cities of Europe are different from American cities or whether they exhibit all of the same characteristics but are merely evolving at a slower pace because affluence came later, their population growth has been slower and there remains a relatively larger mass of historic fabric at the core (Bruegmann, 2005). A good deal of recent research seems to indicate that the American example is not an aberration, but that when cities become more affluent they virtually always tend to decrease in density (Echenique and Saint, 2001). In fact, virtually every urban area in the world seems to be following the lead of the United States in the way overall densities are dropping and development is pouring out into peripheral areas with highways, shopping centers, and residential subdivisions (Angel et al., 2011 and 2012).

This article is a revision of the previous edition article by R. LeGates, volume 24, pp. 16092–16099, © 2001, Elsevier Ltd.

Abstract

This article reviews the scholarship developed in the subject of urban studies. The boundaries of urban studies are constantly in flux. This article examines the questions through which urban studies has become defined and its relationship with other core social sciences, and its place in university education. Urban research and scholarship is frequently interdisciplinary in its practice. Urban research is becoming increasingly globalized in the practitioners involved in it. The call for urban theory to be more responsive to the diversity of the city has challenged the dominance of earlier perspectives. Fundamentally, there is a lack of consensus around its ontological core, what defines the city, and how should it be conceptualized. The article also examines the implication of interdisciplinary and transdisciplinary for the status of urban studies in relation to the core social science subject.

Unpacking urban studies – the questions through which it has become defined, the story of its development, its relationship with the core social sciences, its place in university education – is revealing in helping to identify what contribution urban scholarship has been able to make to the wider project of intellectual endeavor and the problems that have surrounded its development as an autonomous field of study. As a term 'urban studies' invites immediate identification with specific aspects of human life; furthermore, as it has become commonplace to remark, more than half of the world's population is urban. In other words, studying cities – the endeavor of urban studies – should be central to the social sciences just as it should occupy an important position pedagogically in universities. Paradoxically, however, as a term 'urban studies' has a somewhat restricted use geographically, as well as in university curricula, while its status as an autonomous field of study within the social sciences has not reflected the importance the city has to modernity.

Such an argument has been expressed by others who have sought to understand the nature and role of urban studies as an intellectual endeavor; Robert Beauregard (2010) in a recent overview considered that among the social sciences urban studies occupies a somewhat marginal position. Yet, adopting such a position should not be taken that 'urban studies' lacks a core, nor that it lacks theory. Rather that, by comparison with the core social sciences, sociology, anthropology, political science, economics, and human geography, for example, it appears to be a relatively poor relation in (for example) its representation in university social science faculties. Further, while, as will be argued, there is a recognizable core of questions that help define urban studies, by its nature an appreciation of 'the urban' needs to be able to come to terms with the (multiple and growing) number of intersections with human life. Concepts such as 'urban greening,' considering the contribution of cities to global warming, are rapidly assuming an important place in urban research, yet were absent from the field of urban studies little more than a generation ago. In other words, the boundaries of what constitutes urban studies are constantly in flux, enlarging its reach, developments that may further problematize its definition as a discrete area of enquiry.

As an overview this article begins with an attempt to identify the core of what constitutes 'urban studies,' the issues that have been key to its research agenda. The discussion then turns to the problems linked with the studying of cities. The issues underpinning urban studies and its research agenda have unfolded in ways that reflect the changing understanding of the nature of cities and the epistemologies through which they should be studied. The problems of undertaking urban analysis both reflect the complexities of cities and offer some plausible explanation as to why the study of cities, as significant as it is to understanding contemporary (and past) life, does not enjoy a similar position to the core social sciences.

Identifying a Core

Identifying the core of an academic field as broad as urban studies is likely to be both a fraught as well as a contested exercise. To the extent that intellectual enquiry is influenced by fashion, what is understood as constituting the core may change, just as the development of competing epistemologies will foreground different types of (urban) issue. Defining what is the core of urban studies too differs from what *should* be its primary concerns – what research questions should we be asking about cities as opposed to those that are broached.

One route into the question of identifying the core issues of urban studies is to approach it from how cities are studied. In their successful *City Reader* Richard T. LeGates and Frederic Stout (2003) identify 12 key issues that "have most intrigued scholars who study cities" (p. 13) and present key readings representative of each likely to appeal to a wide audience, undergraduates through to scholars working in the area of urban studies (*sic*) and allied fields. In other words, their selection of topics sought to appeal to the wide variety of disciplinary backgrounds with which urban studies is associated. These issues included the evolution of cities; urban culture; urban society; urban politics and governance; urban economics, urban public finance, and regional science; urban and metropolitan space and city systems; megacities and global city systems; urban planning, design, landscape, and

architecture; race, ethnic, and gender relations in cities; urban problems and policy and urban futurism.

What needs emphasizing is that LeGates and Stout identified the range of issues with which urban studies considered in its broadest sense can be associated. Urban texts devised by scholars working from a more disciplinary perspective (e.g., Hall (2006) or Stevenson (2013)) will be more focused and less comprehensive of the range of topics urban studies entails. The concerns identified by Gates and Stout are revealing for the span covered by urban studies, yet while each was drawn out illustratively through key examples and authors involved in the study of different aspects of cities, the presentation was less transparent on the specific questions that have preoccupied urban analysis and which continue to do so.

The key questions around which urban studies has evolved, and which continue to dominate the field, entail those that have been historically enduring, added to which are other newer entrants that have developed particularly as a response to the recognition of the problems cities create or can be associated with. Among the enduring questions are the following:

- Why do cities grow? Why do some cities grow more than others? What are the implications of the uneven growth of cities? How do we understand why and how cities grow against the context of the multiscalar world in which these processes unfold?
- How do we define the city? How do we define and understand cities within the deepening processes of globalization?
- How are cities – their development and social processes within them – to be theorized? Do megatheories of urban structure and change have continued importance for urban analysis or are they too universalist in their claims and therefore better substituted by middle-range theories? How can and should urban theory respond to the urban growth in the global south?
- What methods should we use to study cities? What types of urban process are able to be meaningfully explored through macroscale perspectives as opposed to those more suited to microscale forms of analysis? What are the implications of using different research methods to explore urban processes?
- What defines the nature of urban life? How is social life in the city organized and conducted?
- How are cities governed? How should they be governed to meet the ideals of democracy? How are they governed to meet the aims of achieving economic growth and the delivery of public services in efficient and equitable ways?
- How are the issues of social diversity responded to in everyday life and through urban policy? What problems arise from different patterns of behavior between those living in the city (e.g., antisocial behavior) and how are these responded to through the governance of the city?
- What is the role of the market in the city in influencing the distribution of land uses and the provision of basic needs and what role should the state have in ensuring that these needs – for housing, transport, education, for example – are met?
- What have been and are the implications of new technologies in fashioning urban structure, urban economics, and social change? How can new technologies be used to address urban problems (e.g., Smart Urbanism) and what are its soci(et)al implications?
- How are cities planned and how should they be planned? What are the implications of the planning process for enhancing the economic growth of the city, social life within it, its governance and for local democracy? What is the role of architecture in the planning of cities?

These questions are representative of the more enduring issues that have preoccupied urban studies but do not make a claim to be comprehensive.

The unfolding development of urban studies has been marked by the augmentation of these questions in the light of the changing contexts within which cities are located. In other words, how and why urban studies has developed has often been as a response to the changing environment in which cities function and are represented by economic and political, including policy, shifts. As it has been frequently commented on, the study of cities as an intellectual endeavor has been responsive to major societal problems and shifts – indeed, urban studies has enjoyed major spurts of growth as a response to wider societal crises in the 1920s, the 1960s, and the 1970s and at the present day. Within recent decades the 'enduring questions' of urban analysis have been added to by new questions often in response to the identification of societal problems, the importance of which has propelled them to achieve core status. Two examples can be cited to show how the core agenda of urban studies is expanding and fluid:

- How can more sustainable forms of urban development contribute to reducing environmental problems including climate change? What are the policy and political implications linked to making cities more sustainable?
- How can and should cities be more socially just? How is the just city to be defined and how can social inequalities in the city, an enduring but reemergent feature of them, be addressed?

Again, these new questions do not exhaust how the core of urban studies has been augmented in recent decades, though the question of social justice implicitly refers to how urban neoliberalism is a dominant assemblage of techniques affecting the city in multiple ways, the play of power relations in the city, and the role of resistance.

What the range of core questions amply demonstrates is that urban studies is a multidisciplinary field aiming to understand (and steer) what is a highly complex 'structure.' By their nature, many of the questions may be suggestive of the primacy of particular disciplines. Indeed, how urban studies has evolved reflects this as the analysis of particular questions has developed with the development in turn of new subbranches and their attendant infrastructure such as specialist academic journals. Simultaneously, however, relatively few questions are the exclusive domain of particular disciplines; urban research and scholarship is frequently interdisciplinary in its practice.

Urban Studies in Flux

Few would deny that as a research field the contemporary study of the city is a vibrant and rapidly developing area, the nature of which has changed dramatically within recent decades. Its multidisciplinary nature together with the obvious ways in which its key concerns have such obvious relevance to societal (including global) problems contribute to its vibrancy and significance as an intellectual endeavor.

The vibrancy of urban research is reflected in its professional development. As an exemplar of its development the increase in academic and professional journals catering to urban researchers is one obvious indicator of the broadening reach of urban studies. At the middle of the twentieth century there were no academic journals specifically focused on publishing urban research. This was dependent on journals belonging essentially to the mainline disciplines that endorsed urban research as a branch of their wider endeavors. During the 1960s two journals were initiated, which were wholly focused on publishing urban research, the *Urban Affairs Quarterly* (later titled *Urban Affairs Review*) and *Urban Studies*. Both were responsive to publishing urban research that was interdisciplinary in its focus with papers covering a wide range of different research. Other journals were to follow, in some cases as in the *International Journal of Urban and Regional Research* focusing on theoretically driven, critically oriented research papers, while being responsive to the breadth of the urban research agenda. More numerous were specialist journals identified around the emergence of particular subbranches including *Urban Geography*, the *Journal of Urban Economics*, and *Urban Anthropology*. Whereas, then, at the mid-twentieth century there were no academic journals in the Anglophone world exclusively committed to publishing urban research, some two generations later the number is nearer to 20. Added to this are a growing number of professional journals published in the planning and other fields related to urban development.

Vibrancy too is reflected in the growing geographical spread of researchers drawing in those increasingly from the global south. For much of the twentieth century urban studies was dominated by researchers from North America and particular European and other northern countries, a domination that is hardly challenged by recent shifts but which, increasingly, is being complemented by urban researchers working from the global south. Thus, within the first decade of the twentieth century paper submissions to one of the leading generalist urban journals from China increased from accounting for less than 1% of all submissions to more than 8%. (For the same period the submissions originating from the USA hovered around 20% and, for the UK, a little lower.) The submissions from newly emergent nations closely follows the BRIC and TIGER groupings, but, if at the margins, is beginning to draw in researchers from other less developed nations. In other words, urban research is becoming increasingly globalized in the practitioners involved in it.

Vibrancy too is reflected in the multiplicity of perspectives, theoretical and methodological, through which urban research is conducted. While in the earlier history of the subject the study of cities had tended to be dominated by universalizing theories and arguments, contemporary research is more acutely aware of the intellectual dangers of meta-theory and the influence paradigmatic cities and perspectives can have in framing research in the very different circumstances represented by the diversity of cities. Whereas, then, for much of the twentieth century understanding the social life of the city was influenced by the tenets of the Chicago School, before the end of the century other perspectives had become dominant drawing out in many cases very different forms of analysis. Remnants of the Chicago School remain and, in some cases, the popularity of ethnographic methods of analysis, for example, is being revisited. Further, the influence of the paradigmatic city remains a seductive force in understanding cities. Nevertheless, the call for urban theory to be more responsive to the diversity of the city, global north and south, has challenged the dominance of earlier perspectives (Robinson, 2006; Roy, 2011).

The multiplicity of perspectives through which urban research is conducted makes for it being a broad church but one that challenges the coherence of the field. Fundamentally, there is a lack of consensus around its ontological core, what defines the city, and how should it be conceptualized. It is an ongoing problem that has confronted urban studies at different stages in its intellectual evolution – what is a city? How is it to be defined? Earlier attempts to define the city tended to focus around what it is not, the rural. Yet, such definitions are increasingly challenged by the blurring of the urban and rural and by the increasing awareness of the problems of defining the city in fixed terms in a world defined by rapidly emergent fluidity.

The reality is that as a broad church the research of urban studies embraces perspectives that are mutually inconsistent in ontological and epistemological terms. Positivist forms of analysis remain, particularly in econom(etr)ic analysis, in which the city is defined in fixed terms and in which rigorous, frequently quantitative, scrutiny seeks to claim the identification of 'true' relationships. Alongside such studies are those that embrace a postmodern rejection of the objectivity and totalizing expectations of positivism in favor of interpretations that are more receptive to diversity, ambiguity, and contingency. Whether such epistemological diversity is a source of weakness is a moot point (at least for some), but one that is likely to be challenged by researchers who have sought to embrace the wider 'turns' in social science research, cultural, linguistic, and spatial. In other words, the strength of urban studies as a field is to be sought more through the diversity of epistemologies it adopts and its willingness to embrace new perspectives able to explore the richness and complexity of the city.

Explaining the Status of Urban Studies

Paradoxically, given the apparent vibrancy of urban research and the broadening array of issues around which urban studies has become defined, its position within the social sciences, as suggested at the outset, is marginal. Many of those involved in urban research would subscribe to its contemporary practice being exciting, particularly for its epistemological diversity, even if this eclecticism challenges the coherence of understanding the city and their ability to talk to one another across what are sometimes disciplinary fences. Yet as much as urban

studies is vibrant, its status among the social sciences and particularly to its core disciplines is more one of a relatively 'poor' and dependent relation rather than an equal. To those social science disciplines that have been key in unraveling the nature and working of cities – economics, sociology, political science, geography, and anthropology in particular – the study of cities is a branch or subbranch; at the same time the field defining itself as urban studies has been unable to break into the ranks of what are considered the core social sciences. Explaining the paradox entails reexamining the nature of urban studies as well as it does the wider political environments in which urban research, particularly in universities, is located.

Problems in defining what is the city, which successive urban analysts have sought to explore, is matched by the inherently problematic nature of the urban itself. As a space or an area it tends to cut across the disciplines around which social science has become defined – that is, because of the nature of the urban it is inescapably of interest to political scientists as it is to geographers and sociologists. To the political scientist, then, acknowledging the role of cities, as Mossberger et al. (2012) argue in their keynote volume, follows from its ability "to conceptualise and understand local/urban political processes, public problems, and forms of decision-making to a particular space or location, rather than just analyze the subareas of voting, policy making and social movements…Urban politics is both a field in its own right, with particular dynamics and constraints that vary from place to place; and an area of research that tells political scientists and other scholars much about politics more generally, whether at the local, national or supranational level" (p. 4). Understanding urban politics is important to understanding political processes more generally while, interestingly, the argument also captures the diversity and uniqueness of local urban politics. Yet, to the wider project of political science understanding the role of urban politics is contributory to, rather than a core element of, the discipline. A similar story is repeated in the relationships the urban has with the other core social sciences. There are variations in how the story has evolved, not least because of the evolution of the separate social sciences themselves and the significance of the urban to the central tenets of the disciplines themselves. These variations, however, do not mask the reality that urban analysis in the core social disciplines has at best been a part of them, often qualifying the central tenets of the core disciplines rather than being necessarily central to their identity.

Another way of viewing this positioning of urban studies within the social sciences is to highlight a claim frequently (and rightly) made of it, its multidisciplinary nature. Two points follow from this – that, as it has been argued, the urban overlaps with the interests of multiple social science disciplines, but that, critically, it raises the specter of urban analysis needing to be interdisciplinary in how researching cities is conducted. The first raises the possibility that urban scholarship becomes 'dependent' on the efforts of those working from the perspective of the key disciplines to which it is allied, the second the problem of interdisciplinarity that has been an enduring issue not just to urban studies but to other fields of intellectual endeavor that transcend established frameworks of knowledge understanding, the 'disciplinarization' of knowledge production.

The dependency of urban analysis on the social science (and other) disciplines has had beneficial as well as more problematic impacts. Were we to identify the most influential analyses linked to the city in the last century, this would most likely include outputs from the Chicago School and texts such as Robert Dahl's (1961) exploration of urban power, *Who Governs?*, and David Harvey's (1973) book, *Social Justice and the City*; the list would also include others from outside the social sciences, notably Lewis Mumford (1937) and Jane Jacobs, particularly in *The Death and Life of Great American Cities*. Their influence in the development of urban studies has been indisputable in influencing in turn much subsequent research. Yet, as much as urban research draws attention to its interdisciplinary nature, its researchers have often failed to throw off their disciplinary legacy.

The problem identifies the power of the core disciplines in furthering (urban) knowledge and the challenges in being able to conduct research in ways that are more faithful to the ambitions of interdisciplinarity. Ramadier (2004) proposes a spectrum of disciplinary thinking in which its boundaries are progressively challenged through interdisciplinary and, ultimately, transdisciplinary analysis, arguing that it is really the latter that is able to address the complexity of urban issues. Yet, transdisciplinary analysis remains an aspiration, reliant as it is on the subordination of disciplinary to responsive, new ways of thinking about the city and its problems. Even its 'predecessor,' interdisciplinarity, poses challenges to the ways in which researchers approach urban research. Its realization may be more likely where urban research is conducted around closely defined issues and problems – possibly ones that have distinct policy implications – by teams of researchers representing different disciplinary backgrounds and working cooperatively.

The close connections between urban analysis, the understanding of the major problems of the city, and its ability to inform public policy have characterized the development of urban studies. Responding to the problems of cities – in the 1920s and the 1960s as well as the present day – urban studies has experienced significant shifts in how cities are understood. Further, precisely because the problems cities often tend to experience – poverty, deprivation, crime, racial conflict – can only be understood from a multidisciplinary perspective, so their analysis and their policy prescription has been interdisciplinary in its scope. Thus, the race riots in London in the early 1980s, together with the accompanying problems of urban social and economic deprivation, were to draw in researchers from a wide variety of social disciplines – sociologists, geographers, political scientists – and from beyond, including theologians (Archbishop of Canterbury: Commission on Urban Priority Areas, 1985).

While the development of urban studies has been closely connected with urban problems and policy, the relationship has not always been unproblematic. Urban policy research, and the presentation of policy solutions to urban problems, has run the gauntlet of criticism from other urban researchers for the shallowness of its research and its failure to understand the complexity of the city or, as in the case of the lively debates surrounding Richard Florida's notion of the creative city, the distributional consequences of policy tropes. Further, to the

extent that urban policy-oriented research falls short in the comprehensiveness and depth of its analysis, it can become 'relegated' in qualitative evaluations of research that have themselves become increasingly widespread in national university systems.

A Brief Postscript

Urban studies is defined around a paradox – its ambivalent relationship with the social sciences and its vibrancy. Entrenched systems of knowledge production reflected through the core social science disciplines, the complexity of the city and the interdisciplinary nature of urban problems, the footprint of the urban cutting across disciplinary boundaries, the challenge of conducting interdisciplinary research that is able to meet its demands – each has influenced how urban studies has developed but in ways that have effectively prevented the field from being able to create a sufficiently powerful identity in its right so that it is able to claim an equality to the core social sciences. Such a conclusion would not necessarily be subscribed to by all urban scholars; furthermore, to the extent that the argument carries weight the problem may be in the shortcomings of those involved in urban analysis in being able to fashion a sufficiently rigorous and intellectually autonomous field.

Simultaneously, urban studies is an increasingly rich field of intellectual endeavor. Its productive adoption of the multiple 'turns' – linguistic, cultural, spatial – has been key here. The centrality of cities has ensured that they have been rediscovered not only by the core social sciences but increasingly by scholars from the humanities. As during previous crises in the last hundred years, urban studies has been enriched, a richness that is defined around its epistemological diversity and its (necessary) tolerance to it.

Abstract

In the early twenty-first century geographers continue to examine relations between cities, towns, and what may lie beyond their perceived borders. Yet efforts are now underway to redefine the urban system canon in order to better address questions pertaining to the global system of urbanization. The approach still holds explanatory purchase for both systems of cities and cities as systems. Research agendas have been updated, however. The emphasis for interurban relations has shifted from rank to network – or from national hierarchy to transnational connectivity. Research concerning core–periphery relations at the intraurban scale increasingly takes into account the rise of massively expansive yet functionally integrated polycentric city-regions in virtually every world realm. Nonetheless, poststructuralist perspectives such as mobile urbanism pose further challenges to system-based constructs.

From National Urban Systems to Global City Networks

In the decades of modernization and fast-paced economic growth following World War II, policy-makers concerned themselves with planning balanced and synergistic urban systems within the framework of tightly bounded national space-economies. Ideas influential during this period included the rank-size rule and central place theory. The following three propositions summarize the extensive literature on location theory: cities and towns with known population sizes are regularly spaced across a given territory (Lösch, 1954); predictable decreases in population size occur for nodes progressively ranking lower in the urban system – i.e., the population of the nth-ranked town being reduced to just $1/n$ of the country's largest city (Stewart, 1958); and urban nodes acquire heightened economic importance when they are able to serve extensive market areas with their specialized goods and services (Christaller, 1966/1933). Currently, the systems approach to urban centrality remains the most influential within geography's cognate of regional science, particularly among those focused on developing a general systems theory of urbanization (Hall, 2009).

In an earlier assessment of the urban systems approach, Hall (2001) listed its weaknesses. Despite the theory's purchase on territorial development initiatives of the mid-twentieth century, empirical corroboration was questioned early on. Not only did its proponents assume urbanization to be taking place on an abstract isotropic Euclidean plain; they also required territories to be self-contained with negligible interactions with external regions. Moreover, the field's economistic rationale of purported universal applicability notwithstanding, studies were not able to develop convincing explanations of why the expected regularities could be corroborated in certain regions but not others. Departures from the assumed norm were particularly conspicuous in what was then called the developing world. Urban primacy, a larger-than-expected concentration in capital cities or primate cities, came to be seen as a problematic feature, particularly in countries with burdensome colonial inheritances (Berry, 1961). Furthermore, following Lipton (1977) critics of the 'urban bias' argued that city-centric economic initiatives and aid schemes actually constituted a hindrance to development. This thesis, however, is now being critically revisited. Jones and Corbridge (2010) posit that the major advantages and increasing returns to urban agglomeration also accrue beyond the Global North, where they have been most thoroughly studied by the new economic geography.

In the current era of globally attuned urban geography, it is important to notice that Brazilian scholars have made an important contribution to urban systems research particularly through their studies of urbanization in the Amazon Basin (Becker, 1995; Corrêa, 1987). This body of research is noteworthy because it draws from location theory – by problematizing systemic interurban flows and relations of relative centrality, while also rising above the traditional limitations to this approach. Long considered an anomaly in terms of spatial development, Amazonia is both a vast natural space of planetary significance and a thoroughly urbanized territory with an extensive, albeit unevenly developed and thinly connected, network of cities and towns. While clearly lacking in second-rank nodes, which location theory valued as ideal for a region's integration to the national urban system, the network includes city cores with global ambition, such as Metropolitan Manaus, as well as hybrid settlements; these depart decidedly from rural configurations but are also devoid of even basic aspects of urban infrastructure and economic resources.

Becker (1995) points out that the unusual patterns found in the 'urbanized forest' cannot be properly understood without accounting for geopolitics, particularly the multiple interventions that the Brazilian state has undertaken to develop the region since the 1960s. Adopting a longer-term perspective, Corrêa (1987) emphasizes the need to develop a periodization of the urban network's evolution according to the shifting mode of regional integration to the world system, as e.g., a resource-extraction periphery and then a development frontier for industrial capitalism. Thus, rather than an anomaly to a stylized model of urban system configuration, Amazonian urbanization may be understood more productively as part of

and not apart from the unstable historical geographies of capitalism and the unevenness produced by its dominant modes of production through time. Thus, a geo-historical analysis of urbanization is required not only to chart out the spatial constitution of urban networks but also to examine the drivers of their dynamic evolution through time in a context of capitalist uneven development.

Urban system configurations have also been reexamined at the global scale. Sassen (1991) points out that since the later third of the twentieth century, the organization of production through extensive value chains of transnational reach has promoted the revalorization of select urban economies such as e.g., New York, London, and Tokyo but also Shanghai, Johannesburg, and São Paulo. These now function as command and control centers for the global economy with major clusters of specialized producer services. Concerned with the connectivity and economic specialization of such global cities, a vibrant new frontier of research on urban systems has consolidated around the notion of a world city network (Beaverstock et al., 2004). Earlier versions of this work may have represented a simplistic scaling-up of traditional central place theory notions from national systems to a global economy assumed to be smoothly integrated through transnational networks. These early efforts were also overly concerned with controversial rankings and a hierarchical categorization of world cities. Yet Taylor (2009) has called for a theoretical reorientation to provide a more fruitful conceptualization of intercity cooperation and mutual complementarities implicated in the production of economic globalization.

The Urbanization of the World and Rise of City-Regions

Beyond economistic reductionisms, urban geographers posit that globalization cannot be fully understood without theorizing the expansion of urbanism as the dominant form of social organization worldwide. This assertion rests on the recognition that the conditions for global economic integration depend largely on the unprecedented extent and scale of contemporary urbanization, a process that has also been discussed as generalized planetary urbanization (Brenner and Schmid, 2011). The complexity of resulting spatial patterns cannot be easily captured through traditional urbanization concepts let alone through the urban systems approach. Brenner (2013: 87) points out that geographies of urbanization are "assuming new, increasingly large-scale morphologies that perforate, crosscut, and ultimately explode the erstwhile urban/rural divide."

The city-region constitutes an important example of efforts to re-conceptualize functional specializations at the intraurban scale and core–periphery relations within agglomerations in light of this expansive urban reality. The literature explicitly seeks to move beyond notions limited to the scale of twentieth-century metropolitan urbanization (Scott, 2001). Parr (2005) explains that formal administrative boundaries and even the contours of contiguously urbanized metropolitan cores no longer reflect underlying structures of economic and social organization adequately. Relations between cities and surrounding territories have been re-functionalized. Increasingly widespread and complex, the patterns of interaction have also given rise to polycentric urban regions with multiple, often complementary, and specialized, city cores.

Economic geographers have shown particular interest in the city-region because the concept highlights the ongoing relevance of urban agglomeration and territorialized economies in the age of globalization and the purported end of geography (Rodríguez-Pose, 2008). Methodological questions remain on the definition of areal extents and the conceptualization of how city-regional formation fosters economic innovation and competitiveness (Turok, 2009). Yet, city-regions are increasingly seen as a key unit for growth and development in the contemporary world economy, and the city-regional coordination of infrastructures and economic activities is argued to play a crucial role in the establishment and maintenance of advanced global city centers to service extensive transnational markets (Scott, 2001). Empirically, several studies document the emergence, functional articulation, and increasing policy relevance of regional urbanization in the European Union (Hall and Pain, 2006); China and the Asia Pacific region (Douglass, 2000); and North America (Lang and Knox, 2009). The United Nations has begun to recognize the worldwide emergence of extensive urban configurations that, taking the form of mega-regions, urban corridors, functional city-regions, and massive conurbations, are announced to be the new engines of global and regional economies (UN-Habitat, 2010).

Critical perspectives on the emergence of city-regions also warrant attention. Roy (2009) points out that even though the city-region is becoming one of the dominant notions in the field of urban global studies, its theorization is largely predicated on specific experiences of urbanization in North America and Western Europe and therefore does not reflect other multiple forms of rapid urbanization occurring throughout the entire planet. Robinson (2006) calls for renewed efforts in cosmopolitan, globally comparative research in order to better capture such urban heterogeneity beyond imposed categorical dichotomies of North–South, rich–poor cities usually conceptualized as either entrepreneurially geared to ascend in global city hierarchy or locally focused on remedying developmental deficits. A case in point can be found in Johannesburg. **Figure 1** contains a schematic diagram representing Johannesburg's complex spatial transition from an industrial metropolis in the apartheid era of South African development to one of the cores in the thriving yet still highly unequal and fragmented Gauteng city-region with multiple and heterogeneous connections to the African continent and world economy.

Politics also matter in the making of city-regions. Jonas and Ward (2007) call for more explicit analyses of the role that power relations play in the varying construction of city-regions as territorial entities at the service of diverging political agendas and spatial goals. Moreover, Brenner (1999) demonstrates the centrality of city-regional agendas in wider state projects to reconfigure the economic capacities and rescale the regulatory functions of nation-states transitioning to a global economic order in the face of neoliberal hegemony determining market-centric approaches to urban and regional development. Such politics of scale, however, are far from linear. Institutional contestation and social mobilization mediate their outcomes (Jonas and Ward, 2007). In fact,

Figure 1 Schematic diagram of Johannesburg's spatial transition. Source: July 2006. Urban Age Conference Newspaper "Johannesburg Challenges of Inclusion?" (n.p.), London School of Economics and Political Science. http://v0.urban-age.net/0_downloads/JohannesburgNewspaper.pdf.

city-regional interdependencies provide opportunities for innovative forms of community organizing and coalition-building aiming for more egalitarian forms of urbanization (Benner and Pastor, 2011).

Poststructuralist Perspectives and Mobile Urbanism

Poststructuralist perspectives have also gained influence among geographers and pose additional challenges to the traditional urban system literature by taking on cognate questions of intercity relations and *trans*-local city-making. These efforts, however, adopt a diverging, less deterministic, approach that emphasizes contingent connections among multiple and heterogeneous intervening actions of both humans and the more-than-human world. Scholarship on questions of urban assemblage, and particularly its application to mobile urbanism, provides salient examples. Inspired by the work of French philosophers Deleuze and Guattari and science historian Latour, studies on urban assemblage call attention to multiple processes of becoming, whereby agents/objects of varied materialities come together, transforming each other in unstable configurations that help to explain the contemporary pace and complexity of contemporary urban-global change (Anderson and McFarlane, 2011). Thus, assemblage urbanism holds the promise of less reductive narratives of urbanization and city-making. Yet its place within the broader fields of critical urban studies and geopolitical economy remains in question.

Mobile urbanism has advanced an alternative view of the urban system as assemblage. In a pioneering study, Graham and Marvin (2001) focused on complex networked infrastructures in and among cities with global ambitions, such as e.g., a round-the-clock international airport that is seamlessly linked to a state-of-the-art business district through a multibillion high-speed transit megaproject that bypasses the disadvantaged neighborhoods that lie along the way. These (dis) connections were explicitly designed to selectively enable certain flows – while confining others – to serve goals of selective economic globalization while managing its local consequences within determined territories.

More recent contributions to mobile urbanism focus on the burgeoning global transfer of urban policies and schemes across highly differentiated territorial conditions, leading to 'best practices' in one locality to be soon emulated by many others (McCann and Ward, 2012). Thus, while more challenging to measure and model than economic networks and material flows, traveling policies constitute an additional layer to understand how cities relate to one another in the global era through *trans*-local multifarious connections. Whereas understanding the hegemony of neoliberal ideas provides a useful entry point to trace linkages, Robinson (2011) points out that, as is the case with urban policies related to water and sanitation, there is not only a spread of market-centric approaches but also an important hybridization of territorial schemes shaped by localized political struggles and conjunctures that should not be disregarded.

Urban Violence

Abstract

Urban violence may be sporadic or endemic. Sporadic violence refers to periodic eruptions of communal violence between social groups whereas endemic violence is built into the ecological organization of urban areas by structural conditions in society. Although communal violence often appears to be spontaneous, it is often orchestrated by social entrepreneurs for political purposes. The most common form of communal urban violence in the United States is the race riot. Race riots swept urban America during two periods – just after World War I and during the 1960s – and they erupt occasionally to the present day, usually in response to a triggering event, though research suggests the underlying cause is usually competition for scarce resources. Endemic urban violence varies across neighborhoods and is strongly associated with concentrated disadvantage caused by the segregation of a poor group by race and class. In the United States, high levels of violence are disproportionately concentrated in racially isolated poor black neighborhoods and exposure to such urban violence has been shown to have strong negative effects on health, cognition, and well-being.

Although many people assume that rates of violence are invariably higher in urban areas than in rural areas, this is not necessarily true. Indeed, Pinker (2011) has convincingly demonstrated that rates of violence historically were much higher among foraging and rural peoples and that rates of violent death have steadily dropped with the industrialization and urbanization of society during the nineteenth and twentieth centuries. Although in the United States today violent crime rates tend to be higher in urban than in rural areas (Wells and Weisheit, 2004), once accidents and other sources of violence are factored in, violent death rates are actually lower in rural counties (Myers et al., 2013). According to data from the United Nations, the level of urbanization across nations is only weakly correlated with homicide rates with an r-square value in the single digits (personal computation).

Urban violence occurs in two basic forms: sporadic and endemic. Sporadic violence refers to periodic eruptions of communal violence between social groups, usually defined on the basis of religion, race, or ethnicity. Examples include race riots in the United States, Hindu attacks on Muslims in India, and pogroms against specific groups such as Jews in Czarist Russia or Indians in East Africa (Brass, 1996). In contrast, endemic urban violence consists of ongoing violence, often criminal, that varies across neighborhoods but is built into the ecological organization of urban areas by the structural conditions in society, such as poverty and segregation (Sampson, 2012a).

Communal violence within cities has characterized cities throughout history and generally transpires within a larger system of racial, ethnic, or religious subordination and is directed against a despised or envied out-group. Such out-groups are typically framed as unlikable and incompetent or competent but cold (Fiske et al., 2002). Episodes of communal violence are generally triggered by perceived affronts or injuries to the majority population, real or imagined, and often occur during times of social disorder when normative structures have broken down or are temporarily suspended by dramatic events (Cuddy et al., 2008). Classic examples include violence directed against Jews during times of plague in Medieval European cities (Poliakov, 2003) and the violent confrontations between Hindus and Muslims at the end of the British Raj (Saxena, 2013).

Although communal violence between hostile groups may arise spontaneously in response to precipitating events (Ghassem-Fachandi, 2012), they may also be created deliberately by social entrepreneurs who specialize in the production of riots for political purposes, disguising them as spontaneous acts of self-defense against injustice (Brass, 2011). Horowitz (2001) studied 150 communal riots in 50 countries and concluded that despite their seeming spontaneity, riots are often planned and usually patterned with respect to timing, targeting, and location. According to Brass (2011), actors such as the police, criminals, businessmen, and politicians engage in continuous and often clandestine efforts to prepare for communal violence when an opportunity rises, creating 'institutionalized riot systems' that select locations, plan, rehearse, and refine narratives in advance.

In the United States, the most common form of communal violence over the years has been the urban race riot. During the Great Black Migration that began toward the end of the nineteenth century, African-American migrants from the rural south poured into northern and western cities where they were segregated into black ghettos (Massey and Denton, 1993). As ghetto neighborhoods filled up and began to encroach on white residential areas, the new arrivals were met with escalating violence that culminated in a wave of white-on-black race riots that swept urban America after the First World War (McWhirter, 2011), with two of the most famous examples being Chicago in 1919 (Tuttle, 1996) and Tulsa in 1921 (Madigan, 2001).

Race riots erupted in urban American again in the 1960s, but this time violence was not perpetrated by whites but by blacks rising in revolt against oppressive conditions in the nation's ghettos, venting their anger at the police and other symbols of white authority. The principal actions of the rioters were the burning and looting of ghetto businesses, causing Janowitz (1968) to label the violence 'commodity riots' as opposed to communal riots. Although the Kerner Commission

on Civil Disorders famously attributed the violence to segregation itself, announcing that "our nation is moving toward two societies, one black, one white—separate and unequal" (Kerner, 1988), sociological analyses at the time generally invoked a 'deprivation–frustration–aggression model' in which high levels of poverty and joblessness generated frustrations that exploded into violence in response to a 'triggering event,' such as an instance of police brutality (McPhail, 1971). However, Spillerman (1976) later pointed out that most of the variance in rioting was explained by just two variables: region and size of the black population. More recent event history analyses have concluded that the eruption of racial violence in the 1960s is best explained by intergroup competition for scarce resources such as jobs and political power (Myers, 1997).

Although nationwide urban violence has not swept American cities since the 1960s, race riots did not end in 1970 but have erupted sporadically over the years in response to various triggering events, as in Miami during 1980 (Portes and Stepick, 1993), Brooklyn in 1991 (Waddington, 2007), Los Angeles in 1992 (Baldassare, 1994), and Cincinnati in 2001 (Bronson, 2006). Despite the occasional outbreak of race riots from time to time, the most common form of urban violence in the United States today is endemic, expressed on a daily basis in certain neighborhoods in response to structural circumstances prevailing in the larger urban landscape. Across neighborhoods, rates of violence are strongly associated with material deprivation. Whether the urban area is Stockholm or Chicago, violence is predicted by concentrated neighborhood poverty (Sampson and Wikström, 2008). Although average levels of both concentrated disadvantage and concentrated violence are much lower in Stockholm than in Chicago, the relationship between the two variables follows essentially the same curve (Sampson, 2012b).

The reason why violence and disadvantage are less concentrated in Stockholm is that poverty rates are much lower and there is much less segregation by race and class. Massey and Denton (1993) demonstrated that a combination of high poverty within a group and a high level of residential segregation between that group and the rest of society axiomatically produce concentrated poverty, a fundamental process that is exacerbated by elevated levels of segregation on the basis of income (Massey and Fischer, 2000). Although this explanation was critiqued by Jargowsky (1997), Quillian (2012) ultimately demonstrated that, given a class structure dividing people into rich and poor, concentrated poverty results from a combination of racial segregation, class segregation between racial groups, and class segregation among members of the segregated group.

The spatial concentration of poverty also geographically concentrates any attributes that are correlated with poverty, such as crime, delinquency, joblessness, marital instability, welfare dependency, and substance abuse, thereby creating a very unstable and hostile environment that breeds social disorder and a lack of what Sampson (2006) calls collective efficacy – social cohesion between neighbors characterized by a willingness to intervene on behalf of the common good. Within any urban ecology, the various manifestations and sequelae of material deprivation are highly spatially correlated with one another (Sampson, 2012b). Thus, neighborhood violence is but one of many manifestations of spatially concentrated disadvantage that poor, racially segregated groups routinely experience in American cities, making it difficult for researchers to isolate the specific causes and effects of neighborhood violence from the many other maladies that are correlated with concentrated poverty (Sampson, 2011).

Nonetheless, careful research carried out by Sampson and colleagues indicate that high rates of violence are strongly and independently predicted by low levels of collective efficacy and high concentrations of disadvantage, controlling for a variety of ancillary factors (Sampson et al., 1997; Morenoff et al., 2001; Sampson and Morenoff, 2004; Sampson, 2012b). The likelihood that an individual engages in violence is similarly predicted by living in a segregated neighborhood characterized by high levels of crime and moral cynicism – a belief that legal authorities are ineffective and illegitimate (Sampson et al., 2005).

When poor black households move from segregated city neighborhood into white affluent suburbs, their exposure to neighborhood violence is dramatically reduced (Sharkey and Sampson, 2010). Massey (2004) has argued that long-term exposure to high levels of neighborhood violence produced by the combination of high poverty and high segregation have strong negative effects on health, cognition, and well-being. Children and adolescents are especially vulnerable to the negative effects of violence as exposure may alter the course of brain development to produce long-lasting physical, mental, and emotional problems such as attachment deficits, anxiety, depression, and aggression (Margolin and Gordis, 2004; Finkelhor et al., 2009; Duke et al., 2010). According to research done by Massey and Brodmann (2014), poor black adolescents growing up in the United States experience four times the degree of neighborhood disadvantage and twice the level of peer violence as affluent white adolescents. They go on to show that exposure concentrated neighborhood disadvantage increases the risk of obesity, raises the likelihood of failure at school, and increases the odds of committing a violent crime while simultaneously lowering scores on vocabulary tests and reducing the likelihood of eventual employment as adults. They also find that exposure to peer violence increases the risk of ADHD, school failure, violent crime, and criminal justice involvement and that contrasting neighborhood environments go a long way toward explaining socioeconomic differentials by race and class (Massey and Brodmann, 2014).

Exposure to concentrated disadvantage and its accompanying violence has been shown experimentally to have significant negative effects on mental health and happiness (Ludwig et al., 2012) and to increase the risk of diabetes and obesity (Ludwig et al., 2011). Using quasi-experimental methods, Sharkey has shown that exposure to neighborhood violence reduces children's performance on cognitive tests (Sharkey, 2010) and undermines children's attention and impulse control (Sharkey et al., 2012). Also using a quasi-experimental design, Massey et al. (2013) demonstrate that exposure to neighborhood violence also increases the frequency of negative life events among residents and promotes higher levels psychological distress. In addition, by increasing the frequency of negative life events, which often interfere with work responsibilities, exposure to neighborhood disorder and violence also reduces rates of employment and lowers earnings, while exposure to violence in schools reduces grade achievement among children.

Owing to persistent racism, lagging socioeconomic status, and restrictive zoning in American suburbs, levels of black segregation and spatial isolation remain high in most of the nation's large metropolitan areas (Rugh and Massey, 2013). As a result, in the United States, the foregoing negative effects occur very disproportionately to African-Americans (Massey and Denton, 1993). Indeed, the distribution of black and white neighborhoods by per capita income, crime rates, and concentrated disadvantage barely overlap, meaning that the most affluent African-Americans generally experience worse neighborhood conditions than the poorest whites (Peterson and Krivo, 2010; Sampson, 2012b; Massey and Brodmann, 2014). In the past, black poverty was characterized by the inheritance of racial disadvantage (Duncan, 1969), whereas it is now perpetuated by the inheritance of place disadvantage (Sharkey, 2013). The unique exposure of African-Americans to spatially concentrated disadvantage and violence because of poverty and segregation is the principal reason for America's stalled progress toward racial equality.

Urban Violence and Militarization

Jonathan Mendel, Geography, School of the Environment, University of Dundee, Dundee, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

There is a long history of cities playing key roles in different types of violence and military conflict. Urban violence remains a significant factor in cities today. Urban warfare is increasingly prominent in 'new' wars and there has been a blurring of boundaries between military action 'outside' of states and domestic governance 'inside.'

This article will outline how cities are affected and formed by, and play significant roles in shaping, violence and warfare. Urban warfare will be used as an example of the prominent role of cities in violence, and the article will consider the increasing militarization of 'domestic' urban life. Surveillance will be considered both as an attempt to engage with (fears of) urban violence and as an example of a blurring of military/domestic lines. The article will conclude by considering potential responses to urban violence.

Introduction

This article will begin by outlining a historical context. Urban violence is often presented as purely or predominantly a problem for cities and urban life. However, it will be argued that there is a long-running and intimate relationship between cities and violence, to the extent that they have often been mutually constitutive of one another.

This article will then consider broader questions of urban warfare. This article will look at how 'new' approaches to war have led to what Gregory (2008) describes as a cultural turn in counterinsurgency, incorporating diverse types of action from counterinsurgency as 'armed social work' through to 'urbicide' aimed at eradicating the 'disease' of urban lifestyles. Urban militarization will be shown to impact on policing and control in diverse ways: ranging from increasing use of SWAT-style tactics to military technologies and techniques (SWAT – Special Weapons and Tactics). This article will end by looking at other potential ways out of this militarization and other ways of building urban life and safety.

Urban Histories and Urban Violence: 'The City Is the Result of War'

While violence is often presented simply as a threat to urban life, this belies a far more complex history. Virilio argues powerfully that war and cities have been inextricably linked since the beginning of urban living: for Virilio, "the city is the result of war, at least the preparation for war" and he finds military reasons behind the original concentration of people in cities (Virilio and Lotringer, 2008: 19). Drawing on Virilio's work, Graham (2004a: 1) thus moves beyond a focus just on military action against cities to argue that "[c]ities, warfare and organised political violence have always been mutual constructions." Following such work, this article will argue that rather than cities simply being important targets for violence or places where violence takes place, cities and urban violence are more closely intertwined.

There is a long history of violence against cities. For Hewitt (1983: 259) attempts to destroy urban places go back at least to the ancient Roman assault on Carthage. However, Hewitt (1983: 259) also finds a 'more-than-physical reality' to urban places (which feeds into the sometimes extreme measures that can be taken in the hope of annihilating them). Hewitt (1983: 275) argues that particular aspects of this more-than-physical urban life – for example, high-density ways of living – are specifically targeted in area bombing. Hewitt (2009: 344–345) thus thinks about the bombing of London in World War II as part of a 'preoccupation with demonstration pieces or spectacle': finding links between this and the more recent targeting of cities in 'shock and awe.' Similarly, the 'terrorist' targeting cities speaks both to a desire for publicity (cities are often locations for media organizations, for example) and recognition that these are important places for societies and states.

However, the interplay between cities and violence goes beyond targeting. In ancient warfare, Virilio observes that "defence was not speeding up but slowing down. The preparation for war was the wall, the rampart, the fortress" (Virilio and Lotringer, 2008: 20). Militarization now takes place in different ways, though, and military space is now "a space of time, a space of the rapidity of attack and reaction" (Virilio and Lotringer, 2008: 86). For example, missiles and munitions mean that city walls and fortifications cannot offer adequate defense from destruction by large-scale state violence (even to the limited extent that they ever did). Attempts to protect against the speed of attack – for example, through missile defense systems to defend against attacks with nuclear weapons – have not been realized and there are serious doubts about their feasibility. Even ignoring the limitations of missile defense systems, the openness on which cities depend – for example, substantial amounts of goods (including illegal and gray market goods) move in and out of cities – means that ruling out all potential attacks is not feasible.

The role of the military and militarization is also important here. Inasmuch as it plays a role as a defensive site, the city has always been – at least to an extent – militarized. With everything from city walls and barracks to more opaque military involvement (for example, being used to supply essential goods for conflict and populations to serve in wars) cities have always been, to a certain extent, militarized places. It is, therefore, important to follow Woodward in considering how

military activities "imprint themselves across … spaces, places, environments and landscapes. Furthermore, these military geographies also have a far wider imprint than armed conflict, marking and shaping places and spaces far distant from the points of military engagement – including those that I see from my [Gateshead] window" (Woodward, 2005: 730). This history is visible in many urban landscapes. The location of settlements (for example, on hilltops) often has defensive elements and the structure of cities (for example, inside city walls) also often reflects a defensive role. While some of aspects of urban violence and militarization should be seen as novel, we should start by making clear that it is part of a far longer history.

While this move to modern war may have changed the ways in which cities can work as defensive sites – an acceleration of the possibilities for offense limiting the role of military fortifications – cities certainly have not lost their relevance to contemporary warfare. For Woodward (2005: 730), "if all geographies are military in some way, the actual pursuit of armed conflict is only part of the story." For example, Woodward (2005: 718–719) notes the presence of weapons factories and barracks in urban sites – militaries continue to need access to weapons and personal.

Cities have played key roles in the last century's major wars. They were important in resourcing the violence and then in memorializing the losses (see Edkins, 2003: Chapter 3). While there are complex cultural reasons why urban areas have been the target of political violence (as will be discussed in more depth below), this importance of cities in war has led to the development of multiple ways of targeting cities in such conflict. This is perhaps best-illustrated in Walt Rostow's (1981) strategy for the bombing of Germany during World War II; targets are justified in terms of potential damage to the German war effort and the German state. As will be discussed below, this development of rationalities for the targeting of cities continues in 'new' wars too.

While one would hope that there will not be another world war, cities and violence remain intimately linked today. As Graham (2004a: 5) argues, we see cities '*reemerge*, as *geopolitically* charged spaces.' Instead of offering spaces outside of conflict and militarization, in 'new' wars and newer types of violence cities remain very much caught up in the conflicts of contemporary geopolitics. As will be discussed below, cities have also played and continue to play significant roles in the development of 'new' wars, urban warfare, and terrorism.

Military Operations in Urban Terrain and Vertical Geopolitics

For some time now, it has appeared that the US and its allies have the ability to dominate large-scale, high-technology conflicts in 'flat' open spaces. This was especially clear in the 'Turkey shoot' that ended the 1991 Gulf War, with large numbers of retreating Iraqi troops wiped out from above with relatively low risk to US-led forces (Hiro, 1992: 388–389; Matthews, 1993: 166–167). Echoes of this were seen in the more recent violence in Iraq, where – when Iraqi fighters were grouped together in relatively open spaces – the US was also able to use 'dumb' munitions to kill everyone within a given area at low risk to their forces (Clark, 2003: 44).

However, such dominance is not without consequences. Unsurprisingly, opponents of US-led forces frequently seek not to be wiped out from above. In part, because of the capacity of US-led forces to wipe out opponents when they gather in 'flat' and open spaces, such opponents are increasingly fighting away from this type of space (see Graham, 2004b: 12–13). Instead of massing forces in large open spaces, there has been a move toward 'new' ways of fighting in spaces where targeting is harder. While various nonurban landscapes have been used (for example, Afghan caves have been important), the use of urban areas is clearly most relevant to this article.

There has increasingly been a shift away from the geopolitics of conflict being seen as a 'flat' discourse – pivoting around open spaces – and toward a vertical geopolitics (Graham, 2004b). Faced with the prospect of rapid annihilation should they try to contest US action in 'flat' spaces, opponents of US geopolitical goals are increasingly moving to deploying violence in the vertical spaces of cities. As Elden (2013: 49) argues, "[j]ust as the world does not just exist as a surface, nor should our theorisations of it; security goes up and down; space is volumetric."

'New' wars are thus increasingly urban and, as discussed above, cities are reemerging as prominent and volumetric geopolitical spaces. This has led to the development of strategies aimed at using military violence 'better' in cities and to cities being increasingly theorized as problems facing the deployment of military violence. This article will discuss these two approaches consecutively.

The increasing attention given to cities as spaces and places of military violence is leading to increasing focus on training for and simulation of military action in urban areas; the US military, in particular, has aimed to increase its ability to use violence in urban areas. While this is often linked to military actions as part of the 'war on terror,' one might note an October 2001 publication that was already referring to a "renaissance in interest in military operations in urban terrain (MOUT) within the American military" (Desch, 2001: 2). Two 'conventional' explanations for this are acknowledged: "current world demographic trends suggest that increasingly the population of the world will be urban. Thus, the likelihood of any military operation being conducted in urban areas is also likely to increase. Second, a number of recent catastrophic failures in MOUT – the costly U.S. fight in the Bakara market place in Mogudishu, Somalia, in 1993, and the Russian defeat in the first battle for Grozny Chechnya, in 1994–95 – have refocused attention on the challenges of MOUT operations in general" (Desch, 2001: 2). It is also suggested that "there is another factor that is also prompting the U.S. military to think hard about MOUT. This factor is the dramatically different international and domestic security environment the United States faces now that the Cold War is over [including] the fact of U.S. primacy – there is no single nation or even likely coalition of nations that can challenge the United States in conventional or nuclear combat" (Desch, 2001: 2). Subsequent events – including problems faced by US-led forces fighting in Iraqi cities – have clearly worked to further intensify the attention focused on military operations in urban terrain (MOUT).

This interest in MOUT has led to a range of different approaches, which are having impact in terms of both military and (as will be discussed below) civilian approaches to maintaining order. There has been an emphasis on military 'boots on the ground' (sometimes alongside law enforcement) in attempts to maintain order in cities in the course of operations such as Operation Iraqi Freedom. Large numbers of troops can be needed to do this, to the extent that some have argued that the force requirements for doing so in Iraq exceeded what was available to the US government (Enterline et al., 2009: 250). However, such deployments have also been accompanied by a range of high-technology attempts to engage with cities and urban conflict, with often strikingly different effects. A broad range of technologies – from drones to 'precision' guided weapons to Area Impact Munitions – have been used to surveil urban areas and to deploy violence in these areas (Gregory, 2008). There is a move from the 'flat' spaces of older concepts of geopolitics to violence taking place in vertical cityscapes that necessitate very different tactics – for example, 'boots on the ground' have been needed (bringing an associated increase in casualty levels on the US-led side).

Alongside such deployments of technology, there has been what Gregory (2008) terms a cultural turn in counterinsurgency: a type of 'armed social work' in which local communities and the views of local populations become very much part of the terrain or 'battlespace' in which conflict takes place. While this may seem progressive, it is worth following Gregory by flagging up that this type of armed social work need not be an alternative to large-scale urban military violence; instead, it is intimately linked with violence. For example, a focus on 'precision' weapons and on understanding the urban areas in which conflict takes place can very much exist alongside the use of Area Impact Munitions to destroy all life in significant parts of these areas. It is not the case that a focus on greater cultural understanding will necessarily lead to a decrease in military violence; while this 'armed social work' is clearly aimed at achieving a reduction in insurgent violence, its efficacy at achieving this goal has not been evidenced.

Alongside this move to more 'boots on the ground,' there are (potentially science fiction-inspired) dreams of new ways of doing urban violence. There are hopes that increasing surveillance and precision targeting might render city spaces flat and replace 'our' boots on the ground with machines (Graham, 2008). Again, though, this approach to MOUT has not been shown to work with current technologies.

Killing Disease and Killing Cities

The difficulties caused for militaries by these vertical spaces can mean that these spaces are conceptualized in diverse and often deeply troubling ways. Urban life and the structures of urban areas can be conceptualized as a problem for military intervention; part of the goal of intervention is to 'treat' this problem. As Graham (2003) argues, this has led to particular types of urban life being seen through disease metaphors: for example, to conceptualizing "Palestinian urbanization as a 'cancer' whose spread is undermining the organic constitution of the modern State of Israel." Types of urban violence or disorder can then be viewed as part of the disease, while large-scale military violence may be constructed as somehow cleansing or healing of the disease. This discourse can lead to everything from calls to simply destroy significant urban areas through area bombing or large-scale military operations through to attempts to 'treat' the illness through counterinsurgency operations.

The idea of urbicide is significant here – attempts to kill cities, to make urban life impossible, can be presented as 'surgery,' as the use of military, police, or economic violence to destroy 'sick' urban life so that the 'healthy' can be saved. The term 'urbicide' has been used in a range of ways. Berman (1987) introduced this idea in order to describe how "[t]he physical and social destruction of the [South Bronx] began with the construction of the Cross Bronx Expressway in the late 1950s and early 1960s spreading gradually southward … then in the early 1970s the disintegration began to spread at a spectacular pace, devouring house after house and block after block, displacing thousands of people like some inexorable plague." This meant that, where blocks of housing had once stood, the city "now contained nothing at all. Most of the rubble from their buildings had long since been carted away and they were as open and empty as the desert." For Shaw (2004), though, urbicide is more explicitly violent: "a form of genocide, the fundamentally illegitimate form of modern war in which a civilian population as such is targeted for destruction by armed force." For Coward (2004) this is targeted at destroying heterogeneity – at destroying a plural culture.

'Treatments' for urban life might thus go so far as urbicide. This can range from 'unbuilding' programs of planning decay (see Graham, 2004c) through to violence being deployed in much more literal ways – as in Coward's (2004) discussion of the targeting of heterogeneity. State action that goes so far as to deliberately destroy essential urban infrastructure can be presented as a move to save the body politic by destroying the diseased tissue that is supposedly parasitic upon it. A market for weapons-come-redevelopment-tools such as armored bulldozers – to be used in modifying and demolishing urban areas where violent conflict is taking place – has thus emerged: redevelopment and counterinsurgency offered by a single machine (Gregory, 2008). This militarization and these metaphors feed into particular types of urban violence, which continue the long history of complex interrelationships between urban areas and conflict but also offer some novel features.

Policing

The mutually constitutive nature of cities and war is not just visible in such stark examples as cities contributing to war efforts, being targets of military violence or being places where insurgency takes place. Increasingly, there is a blurring of lines between 'military' violence abroad and 'domestic' law enforcement and control within state boundaries. Military technologies and techniques are increasingly being turned inwards and metaphors of a 'war on terror' have led in some circumstances to an escalation of violence and an escalation of the tactics that are viewed as justifiable within the 'domestic' sphere.

For example, Balko (2013: xvi) documents a move to 'SWAT'-style policing in some US cities on some occasions:

military technology proliferated, and war metaphors (for example, the 'war on drugs' or 'war on terror') were applied to policing. Fisher (2010: 5) sees SWAT-style and militarized approaches to and equipment for policing increasingly becoming part of – and militarizing – routine duties such as crowd control. The same military theories of 'new' and networked wars that have been influential in developments in military doctrine (e.g., Arquilla and Ronfeldt, 1996) do not offer a clear divide between war and 'domestic' violence. Instead, theories of net war have long conceptualized a spectrum of opponents from 'terrorist' groups that aim to kill civilians through to wholly or largely peaceful protest groups.

There has also been a militarization of urban policing through drawing on military surveillance technology and techniques for policing uses. Drones have been marketed – and used – for policing within the US: what Wall and Monahan (2011) call a 'drone stare' has moved from Afghan and Iraqi war zones into US cities. Data-led surveillance has also pulled much of the virtual chatter of urban life into a blurring of military-policing boundaries: one of the interesting aspects of recent revelations regarding National Security Agency and Government Communications Headquarters actions has been moves to allow military agencies notionally targeting those 'outside' the state to increasingly conduct surveillance domestically, and for policing agencies 'inside' to work with military agencies 'outside' in order to access intelligence on citizens.

Likewise, military and militarized technologies and techniques are used in the hope of finding – in these data – ways to detect a 'terrorist' before they have even been radicalized. Consortia of military, arms and security companies are working to monitor the ways in which people live in, move through and travel from cities – in the hope of finding some 'print' in these data from which our future proclivities can be predicted (Hall and Mendel, 2012). In contrast to hopes that cities may provide a space of openness and possibility, the figurative violence here lies in a closing down of the future (which may also feed into the far more literal violence of the detention of citizens the restriction of the ways in which some 'suspect' people can live in, come to and move between cities) (Hall and Mendel, 2013).

Clearly, various types of nonstate violence can be part of urban life. A lot of attention is frequently given to the spectacular violence that one occasionally – but too often – sees in terrorist attacks. These attacks are horrific for those caught up in them, and for those who lose people close to them as a result. Such attacks are, however, also thankfully uncommon. There are reasons why people may be especially concerned about this type of violence as opposed to more 'everyday' risks that come with urban life, but clearly there are many things in the city, which are far more likely to harm one than terrorist attack: ranging from road traffic to more commonplace crimes. Cities also remain attractive places to live. One should, therefore, be cautious about militarized responses to the diversity of urban life, which are framed as responses to spectacular and horrific, but thankfully very rare, terrorist violence: such militarized approaches carry real costs, and risk damaging significant aspects of urban life.

This is not to say that one can find any complete escape from the entangling of war and the city, but I would emphasize the opportunities within and beyond the war machine. While Deleuze and Guattari (1988: 214) are right to warn that "[t]here is fascism when a war machine is installed in each hole, in every niche," I would also follow their emphasis on the multiple lines of flight that remain possible for and from war machines. Thrift (2005: 337) responds to Virilio's theorizing of the city by arguing for "social science research on the city that makes it possible to construct a somewhat more hesitant account, not least … because hesitant accounts are closer to the way the world is." Thinking about and engaging with urban violence and militarization might let us find ways to hesitate and to rethink the long-standing relationship between war and cities in some different ways: finding lines of flight that do not end in war, violence, or urbicide.

Conclusions

As this article has shown, there is a long history of the coevolution of cities and war and military-city links are longstanding and still developing. This is very visible today through urban warfare, MOUT and increasing surveillance, control and militarization. Clearly, violence takes place in and has been deployed against cities in some horrific ways. However, there is also hope for ways of developing urban life that do not simply feed into this militarization and violence. I would argue that there is a real imperative to build and develop such approaches.

Urban violence is a serious issue for many, and impacts on people's lives in diverse ways. However, it is also worth noting than many people continue to choose to live in cities. While cities may be targeted, they can also be remarkably hard to destroy. Urban life can persist, even during and after brutal assaults. While war and violence are often viewed as solely disruptive to urban life, this article has instead detailed the mutually constitutive nature of cities and certain types of urban violence. It is also, though, worth looking at other responses to perceived urban threats and violence – reactions that may build on this militarization to offer lines of flight beyond it, or that may offer alternatives or challenges to it.

Doreen Massey (1993: 66–67) draws on the example of a walk down her local Kilburn High Street in order to illustrate a progressive sense of place in the city: taking real joy in the noise, bustle, and diversity of urban life. Against an excessive emphasis on threats of terrorism and against the increasing militarization and surveillance of urban life, I would highlight the importance of making space for this noise and disorder (see Mendel and Riesch, forthcoming). The 'medicine' often proffered in the name of making urban life safer and offering protection from violence may be far more dangerous than the 'illness.' States can still project significantly larger scale violence than any nonstate terrorist group is likely to in the foreseeable future, and moves toward increasing surveillance and a closing down of future possibilities and uncertainties also threaten the freedoms and opportunities that make urban life so attractive. The complexities of cities' vertical geopolitics offer pleasures and possibilities that cannot be found in (literally or metaphorically) 'flattened' places.

One of the responses to the 7 July 2005 attacks on London was the *we're not afraid* campaign: a refusal to respond to terrorism by bowing to fear. Responses in London included initiatives that built a sense of urban community as part of a robust response to terrorism: for example, supporting those

who felt nervous after the attacks in their use of public transport. The response to urban violence – even quite horrific violence – thus need not always or not only be a crackdown or an increasing curtailing of possibility: creative responses that build on and strengthen urban communities are also real options. Rather than accepting ever-increasing surveillance and militarization in response to the perceived threat of terrorism and other urban violence, I would argue instead for a refusal of fear and for attempts to build a more progressive sense of place and city. Rather than bowing to measures which – although nominally aimed at protecting cities – risk destroying what makes urban life so attractive, a refusal of fear and a refusal of certain control measures may let the noise and bustle of cities continue, even if the price of doing so is accepting some risk of nonstate urban violence. While acknowledging the codevelopment of cities, war, and violence I would hope – albeit hesitantly – that urban life still offers lines of flight in more progressive directions.

Acknowledgments

I am grateful to Nicholas Fyfe for his helpful feedback on this work, and have also benefited from discussions with students as part of Dundee University's *Cities* module. This article also draws on ideas discussed with Hauke Riesch, as part of our work on a different topic.

Urbanization

Gordon McGranahan, International Institute for Environment and Development, London, UK

Abstract

The world's population growth in coming decades will be predominantly in urban Asia and Africa. With about half of the world's population now urban, the salience of the rural–urban dichotomy is declining: urban densities are decreasing; polycentric regions are on the rise; and the cultural, social and economic distinctions between rural and urban are increasingly blurred. Nevertheless, urbanization provides critical opportunities and challenges for sustainable development. Urbanization and economic growth have combined to create various global environmental pressures, and often bring social and economic inequalities. However, dense urban settlement has environmental advantages, and measures to inhibit urbanization often exacerbate inequalities.

Background

To say a country or region is urbanizing implies that it is becoming more urban. Demographers have interpreted this to mean that a growing share of the population lives in urban settlements, with the level of urbanization being the urban share, and the rate of urbanization being the annual growth rate of this urban share (United Nations Population Division, 2014). Many other urban researchers also define urbanization in this way, but the term can also refer to land use, economic activity, or culture becoming more urban; and sometimes carries with it the presumption that these different dimensions of urbanization occur together. Increasingly, they do not. Indeed, some of the conventional distinctions made between rural and urban settlement patterns, economic activities, and cultures are becoming increasingly blurred. Moreover, the implications of demographic urbanization can be different from when economic activity, cultural norms, or land use becomes more urban. For example, demographic urbanization implies a shift in population from less- to more-dense settlement patterns; whereas the conversion of rural to urban land, sometimes described as urbanization, is increasingly the result of a shift from more- to less-dense urban settlement patterns.

For this article, the demographic definition will be used. The next section reviews estimates of past and future urban populations and urbanization levels, relying heavily on the official United Nations statistics (as indicated in **Box 1**, these statistics need to be interpreted with care). Globally, we are at a point where the rates of population growth, urbanization, and urban population growth have all been declining for decades, but the number of additional people living in urban areas each year is just peaking, and accounts for virtually all of the world's population increase. The following section looks beyond the narrow rural–urban dichotomy to consider changing settlement forms and rural–urban linkages. The final sections examine urbanization and the challenges and opportunities it creates for economic development, social inclusion, and environmental health and sustainability.

Estimates of Past and Future Urban Populations and Urbanization Levels

Contrary to popular claims, contemporary urbanization and urban population growth rates are not unprecedented. Sub-Saharan Africa is not the fastest urbanizing region now, let alone in history. As described below, available estimates indicate that average world urban growth rates have actually been declining since at least the 1950s, and those for Sub-Saharan Africa since the 1970s (United Nations Population Division, 2014). Urbanization rates are highest in Asia and global rates have been declining over the past half century. Both urbanization rates and urban growth rates are predicted to continue their descent.

The absolute increase in urban populations each year *is* unprecedented, however. Despite the declining growth rates, the estimated annual increase in the number of urban people in the world is just peaking at almost 80 million, though it is now set to begin a slow decline. The United Nation's urban population projection for 2010–50 has an additional 940 million urban dwellers in Africa and 1450 million in Asia (United Nations Population Division, 2014). These two population increments combine to form over a third of the estimated urban population of the world in 2050, and as illustrated in **Figure 1** are about the same magnitude as the overall population growth predicted for the period. Accommodating this many more urban dwellers efficiently and equitably will be difficult.

It can be helpful to think of these urban demographics in terms of two stylized transitions, which are overlapping, interrelated, but distinct. The first, known as the demographic transition, posits that when modern socioeconomic development leads to falling mortality rates in previously stable populations, the population size grows until fertility eventually falls to the point where the population again stabilizes, at lower mortality and fertility rates (Dyson, 2010). The second, known as the urban transition, associates modern socioeconomic development with a shift from a predominantly agricultural population living mostly in dispersed rural settlements toward a predominantly urban-based population engaged mostly in industrial and service activities.

The first set of rows in **Table 1** illustrate the changing overall population growth rates for major regions of the world, and conform roughly to the demographic transition. While population growth rates are now low or falling in all regions, European and North American population growth rates have been the lowest, with the European rates now close to zero (despite migration into the region). At the other extreme, the population growth rates in Sub-Saharan Africa are still well above 2%. Growth rates in Asia and Latin America have been declining particularly rapidly, with Asia's decline having started

Box 1 Interpreting and misinterpreting international statistics on urban populations

Using Different Definitions of 'Urban'

There is no international consensus on how to identify or determine the boundaries of urban areas, as evidenced by the diversity of national urban definition summaries in the reports on Urbanization Prospects by the United Nations Population Division (2014). Definitions may prioritize population criteria (e.g., settlement size), functional criteria (e.g., the share of the working population engaged in agricultural activities), or administrative criteria. The United Nations has tried to keep a degree of conformity in the sorts of settlements labeled 'urban.' Nevertheless, among countries with size criteria, the minimum size generally ranges from 1000 to 5000. Outliers include Sweden, where a built up area with at least 200 households with gaps of no more than 200 m between them is defined as urban, and Mali where the censuses up to 1987 used a cutoff of 5000, the 1998 census used a cutoff of 30 000, and the 2009 census used a cutoff of 40 000. Attempts to come up with internationally comparable definitions have relied mainly on size and density criteria (World Bank, 2009). As the resolution and availability of remote sensing data improve, users of new data systems may be able to apply their own urban definitions, based on variables such as density, contiguity, and distance (Montgomery and Balk, 2011). For the moment, however, there is little standardization or flexibility, and for most purposes, country-specific definitions of urban settlements must be accepted.

Confusing Urban Population Growth and Urbanization

Urbanization is often treated as equivalent to urban population growth. Thus the Wikipedia definition of urbanization at the time of writing this (18 January 2013) states that: "Urbanization refers to the increasing number of people that live in urban areas." However, only about half of estimated global urban population growth can be ascribed to the increasing share of the population that is urban (i.e., to urbanization), the other half being the result of natural population growth. Thus, the world's population between 2000 and 2010 is estimated to have grown at 1.2% per annum, and the urbanization level is estimated to have been growing at 1.0% per annum, and the urban population growth rate has been 2.3.

Relying on Old Census Data and Simplified Population Projections

Reliable estimates of rural and urban population have long depended on national censuses, which aspire to complete counts of everyone in the country, in their place of residence, at the time of the census. Modern technology is slowly rendering enumeration-based censuses obsolete, particularly in countries with well-developed registration systems; and in Western Europe, registration-based and mixed censuses are becoming the norm. Most other international estimates of urban and rural population still rely heavily on enumeration censuses undertaken every five or more often ten years. Even censuses are likely to undercount the homeless, illegal, or unregistered migrants and people living in informal settlements. Moreover, censuses can also take several years to process and release, and in low income or politically unstable countries censuses are often delayed or even canceled. Thus current as well as future population estimates rely on projections. Unfortunately, United Nations projections, on which most researchers depend, are in need of improvement to reduce systematic bias (Bocquier, forthcoming).

more recently. These differences are consistent with the contrasting economic situations in the different regions, with Europe and North America the wealthiest regions, Sub-Saharan Africa the poorest, and Asia quite mixed but with many of the most rapidly growing countries.

The second set of rows in Table 1 contains the urbanization rates, which together with Table 2 reflect movement along the urban transition. Asia is currently the fastest urbanizing region, with an average urbanization rate estimated at 1.4% this decade, with China in particular both urbanizing and growing economically very rapidly. Sub-Saharan Africa is also still urbanizing at about 1.3%, and its urbanization rate is declining more slowly than Asia's, with the result that by the 2020s Sub-Saharan Africa is projected to be urbanizing faster than Asia. With the exception of North Africa, all the other regions are urbanizing at well under half a percent a year, which is consistent with all of them having had more than two thirds of their populations living in urban areas in 2010 (see Table 2).

Figure 1 Population estimates of the world 1950–2050 by rural/urban and more/less developed regions. Source of Statistics: United Nations Population Division, 2014. World Urbanization Prospects: The 2014 Revision [Online]. Available: http://esa.un.org/unpd/wup (accessed 21.07.14.).

The third set of rows in Table 1, the urban population growth rates, are (approximately) the sum of the population growth rates and the urbanization rates. Sub-Saharan Africa's 4.0% urban growth rate this decade is the highest of any region, despite being well below the 5.5% registered in the 1950s. More than half of this growth can be accounted for by its high overall population growth rate. Asia, by way of contrast, has a lower (2.3%) urban population growth rate, but more than half of this growth reflects urbanization.

While the demographic and urban transitions can help make sense of the statistics summarized in Tables 1 and 2, the underlying relationships and drivers are still unclear and the generalizations underpinning the transitions hold limited predictive power or policy relevance. Considerable debate remains over the principal shifts in the demographic transition, including why, when, and for whom health improves and mortality rates decline, and whether the primary driver of fertility decline is, for example, changes in education (Lutz and KC, 2011), urbanization (Martine et al., 2013) or better access to contraception (Cleland et al., 2012). The relationships between the two transitions are also poorly understood, with many observers treating them

as largely independent but some presenting the urban transition as driven primarily by the demographic transition (Dyson, 2010). Moreover, the relationship between urbanization and socioeconomic development is interpreted in widely divergent ways.

More important, the superficial inexorability of the demographic and urban transition models hide the human struggles involved in urbanization – the conflicts it engenders, the opportunities it creates, and the enormous individual and collective ingenuity required to overcome the challenges it brings. A simplistic perspective on urbanization can be accentuated by presenting the process of urbanization in narrowly statistical terms, as being driven by people migrating from rural to urban locations or living in locations that are being reclassification from rural to urban. This presents urbanization as a relatively passive process, involving one decision to move or perhaps no moves at all. Actually, people often move back and forth between and among rural and urban areas and urbanization occurs as much through decisions not to go back to rural areas as it does through decisions to move to town. Moreover, reclassification is generally linked to population growth in previously rural localities; and migration is likely to be a bigger factor in the growth of peri-urban populations as well as in a large share of the small towns becoming urban, rather than in existing urban areas.

Moreover, conformity to the demographic and urban transition models can also hide the enormous variety of forms that urbanization can take. Urbanization is an open-ended process, locally and globally. At the local level, it is difficult to predict

which towns and cities will succeed and prosper and which will wither, and what the consequences will be for the urban and rural economies and environments. Seemingly small differences in initial conditions and in the choices taken and changes imposed along the way, can make all the difference. It is also difficult to predict the increasingly global economic and environmental consequences of the system of cities that form the core of the world economy and its dominant sources of culture. It is particularly difficult to disentangle the role of urbanization in transforming the world we live in from the economic, cultural, and technological shifts that tend to accompany urbanization.

Moving beyond the Rural–Urban Dichotomy

It is often pointed out that 'rural–urban' should be understood as a continuum rather than as a dichotomy, though there are at least two continua. One extends from the urban center through the ambiguous periphery into the rural hinterland. The second extends across settlement sizes from the urban megacity, through the ambiguous small towns, down to the isolated rural hamlets and homes. But the very treatment of settlement as occurring in distinct clusters is also a crude and increasingly inaccurate simplification.

At least since the 1980s it has been recognized that some large population concentrations are best conceived as polycentric urban regions. Also, in some parts of the world conventionally 'urban' activities and livelihoods are increasingly found in areas of low density and small settlements. This is not just the outcome of the sprawl and suburbanization of settlements in affluent countries, but also of the sort of transformations ongoing in low- and middle-income countries.

With the urban–rural distinction is losing its salience, researchers have suggested that the classification of settlement forms should be reworked, using a multidimensional approach (Champion and Hugo, 2004). Such a reclassification is likely to emerge slowly, along with changes in mapping and information technologies. But even when considering urbanization in the more traditional sense, it is important to take into account the changing distribution of settlement sizes and forms, changing urban densities, and the relationship between urbanization and rural–urban linkages.

Changing Settlement Sizes and Locations

Settlement population statistics give no indication of sizes around which a disproportionate number of urban settlements cluster or where population growth is particularly rapid. As urbanization has progressed, even with a stable distributional form (Henderson, 2010), the number of large cities has increased. The number of cities with populations over a million grew from 2 in 1800 to 380 in 2000 (Satterthwaite, 2013). More recently, the number of megacities has been growing, from 10 in 1990 to 23 in 2010, with their share of the world's urban population growing from 6.7% to 10.3% over this period (United Nations Population Division, 2014). Nevertheless, in 2010, over half of the world's urban population was still estimated to live in settlements of under half a million.

Over the last two centuries, cities have also shifted their center of gravity from heavily populated Asia toward Europe and North America, and then more recently back toward Asia again. Thus while at the start of the nineteenth century 63% of the world's largest cities were in Asia this had fallen to 22% by the start of the twentieth century; but it was back up to 49% by the start of the twenty-first century (Satterthwaite, 2013: p. 239). These shifts are somewhat similar to those that have been documented for the world's economic center of gravity (Quah, 2011).

In interpreting statistics on the cities in different size categories, it should be kept in mind that the forms of urban settlement are changing along with the sizes. This can easily lead to misinterpretations. Peri-urban growth, declining urban densities, and the increasing prevalence of polycentric urban regions have become part of the new urban transformation. When smaller urban centers in polycentric urban regions grow more rapidly than the larger centers, this can be interpreted as reflecting a shift in population growth toward smaller settlements or as a change in the form of large urban agglomerations; but it is not reducible to either.

Changing Urban Densities

Suburbanization, sprawl, and other manifestations of declining urban densities have been observed in affluent countries at least since the early nineteenth century and particularly in North America where the shift to the automobile was vigorously promoted. Urban densities have also been declining, though less dramatically, in all other major regions of the world. A major recent study of urban settlements with populations over 100 000 (Angel et al., 2011) concluded that average built-up area densities declined at about two percent between 1990 and 2000, with urban land cover growing at about twice the rate of urban population.

Unplanned, low density urban expansion, or urban sprawl, is often blamed for creating settlement forms that are environmentally damaging (Wilson and Chakraborty, 2013) and unhealthy (Frumkin et al., 2004). Damaging sprawl can result from not taking these environmental and health impacts into account when infrastructural and residential decisions are being made, and it is sometimes amplified by 'perverse' subsidies. Particularly in affluent countries, sprawl is often presented as something that smart growth and compact cities need to work against. In lower income countries, declining density can push affordable housing far out from city centers; and finding better ways of reconciling density with healthy and convenient housing for lower income residents is often a major challenge.

Urbanization and Rural–Urban Linkages

Urbanization is often treated as something that just happens in urban settlements, though by definition it involves a shift in population from rural to urban locations, transforming rural as well as urban landscapes and livelihoods (Tacoli, 2006).

Urbanization involves changes in demographic, economic, and environmental flows between rural and urban areas, though not always in predictable ways.

Many families in rapidly urbanizing countries adopt livelihood strategies that span the rural–urban divide. They may invest in securing an urban foothold for at least some family members for at least some periods of time. Rural-bound remittances from urban workers often make up a significant share of the incomes of these multilocal 'households.'

Rural–urban linkages have been identified as an important influence on progress toward the Millennium Development Goals (World Bank, 2013a). Indeed, in reading the following section on urbanization and development, it is important to keep in mind that many of the advantages that cities can provide depend on healthy economic and environmental relations with rural areas; and rural livelihoods and environments depend on what is done in cities.

Urbanization and Sustainable Development

Urbanization and Economic Development

Cross-country data show that higher levels of urbanization are associated with higher per capita incomes, with some scatter and some shift in the relationship over time (see Figure 2). Considerable theory and empirical evidence support the view that urbanization is integral to economic growth. Whereas for agricultural and subsistence economies, it is more productive for people to be dispersed, industry and services favor urban clustering. In the language of urban economists, agglomeration facilitates sharing (e.g., of large facilities), matching (e.g., of jobs and people) and learning (e.g., about more productive ways of working) (Duranton and Puga, 2004). The advantages of urban locations are less tangible for postindustrial production but include advantages of face-to-face contact that electronic communications have not managed to replace (Storper, 2013; especially Chapter 11).

Not all aspects of urbanization are economically advantageous. Sharing, matching, and learning, as well as low transport and communication costs, depend on having people and enterprises being located conveniently in relation to each other. People and enterprises tend to seek out economically advantageous locations and given the opportunity, will seize many of the economic benefits of agglomeration. However, they will also create urban crowding and congestion. Reconciling the various conflicting private and collective interests in cities is a major political and governance challenge. Even strong adherents of the market economy acknowledge that people in urban areas are especially dependent on good government, and not just to defend property rights. Cities are shot through with interrelations and impacts that are external to the market; the benefits of urbanization and the people to whom they accrue, depend on how government agencies and other powerful actors and organized groups plan for and respond to these externalities. Notably, many cities have shown themselves capable of contributing to economic growth despite creating serious social and environmental problems.

Given the potential economic benefits of urbanization, and the attraction of most governments to economic growth, one might expect officials in urbanizing countries to favor rapid urbanization. However, the standard survey of world population policies from 2011 found that 82% of developing countries said that they had implemented policies to curb rural–urban migration (United Nations, 2013). Less than 3% claimed to have policies to encourage rural–urban migration, though it is noteworthy that China was among this small group.

Antiurbanization sentiments among officials in Africa has probably been amplified by a tendency to confuse urban growth with urbanization and to exaggerate the speed at which Sub-Saharan Africa is urbanizing (Potts, 2012; Satterthwaite, 2007). Influential research from the World Bank at the start of the 2000s also portrayed Africa experiencing 'urbanization without growth' (Fay and Opal, 2000), reinforcing a widespread view that urbanization should be curbed. However, later

Figure 2 Levels of urbanization plotted against real GDP per capita, 1980 and 2010. Source of statistics: World Bank. 2013b. World Development Indicators [Online]. Available: http://databank.worldbank.org/data/views/variableSelection/selectvariables.aspx?source=world-development-indicators (accessed 27.09.13.).

and more thoroughly researched publications by the World Bank have reversed this interpretation (World Bank, 2009).

A recent review of the evidence that urbanization contributes to economic growth, focusing especially on Asia and Africa, concluded that urbanization has the potential to promote growth and does so when the infrastructure and institutional settings are conducive (Turok and McGranahan, 2013). Even when there is urbanization without economic growth, urbanization can be economically beneficial. If, for example, a country's rural economy is in crisis, pushing people to move to urban areas, the result may be urbanization with economic decline. However, if cities take measures to curb this migration, this is likely to make economic conditions worse, particularly for the aspiring migrants. Of course, the potential economic benefits of urbanization are no justification for leaving rural problems to fester or starving agriculture of productive investment.

Urbanization, Inequality and Social Exclusion

Those who support urbanization as a means of economic advancement generally accept that it also tends to be associated with rising inequalities (Kanbur and Venables, 2005), part of which involves rural–urban differences. Intraurban inequalities are also of growing importance. Even according to conventional income-based measures, a growing share of world poverty is located within urban areas (Ravallion et al., 2007) and most conventional measures miss the depth and scale of urban poverty and inequality (Mitlin and Satterthwaite, 2013).

Somewhat paradoxically, while urbanization is often associated with growing inequality, measures to inhibit urbanization can amplify these inequalities. There are a number of clear examples of this, even among the more successful emerging economies of Africa, Latin America, and Asia (McGranahan and Martine, 2014). South Africa's apartheid system, built around racial controls on urbanization, was not only among the most oppressive systems of urban exclusion when it was in operation but it also left a legacy of spatially and racially fragmented cities. Brazil's more passive resistance to urbanization contributed to the emergence of its favelas, which are also at the center of many of the country's current conflicts and social and economic inequalities. While less clear, China's rural–urban migrant controls, the *hukou* system, could leave a legacy of social and economic inequality and fragmentation.

The exclusion of rural–urban migrants from cities is often bound up with the exclusion of low-income urban populations from urban benefits. UN-Habitat estimates that about 45% of the urban population in developing countries live in 'slum' households, defined as those lacking improved water, improved sanitation, adequate space or solid construction – up from 35% in 1990 (UN-Habitat, 2012: p. 150). A large but 'difficult-to-estimate' share of this population lives in what have come to be termed 'informal settlements,' which represent a 'grey zone of urban exclusion' (Koonings and Kruijt, 2009). Many of these disadvantaged urban residents cannot afford to secure housing in formal markets or through public provisioning. They may not be physically evicted from their cities and towns, but end up living informally, or even illegally, in locations where neither private nor public ownership controls are tightly enforced. Though the net effect is not clear, this intraurban exclusion of disadvantaged groups makes it more difficult for low-income migrants to take advantage of urban benefits and almost certainly pushes some to spend more time in rural areas.

Of course rural exclusion can also exacerbate inequalities and create social problems, and during urbanization the most inequitable outcomes are likely to arise when the same social groups are being excluded from both urban and rural locations. In rural areas, exclusion may come about through policies favoring land consolidation and the increasing dominance of large commercial farms but it can also come about through rural economic decline and population growth. The relatively well-educated and wealthy rural residents may find it relatively easy to find alternative places to work and live in urban areas. Particularly if no efforts are being made in urban areas to accommodate their growing low-income populations, the less educated and poorer rural residents will find it difficult to secure an urban home and livelihood.

Urbanization and Shifting Environmental Burdens

In recent centuries, economic development has shifted the principal locus of urban environmental burdens from local to city-regional and eventually toward global scales (McGranahan et al., 2001). Looking across urban centers in different parts of the world, the poorest urban populations in the poorest countries tend to have the worst environmental health conditions in and around their homes. The ambient environments of heavily industrialized and motorized cities of middle-income countries tend to be most environmentally distressed, with the worst ambient air pollution problems. It is the populations of the wealthiest cities that have the largest global environmental footprints per capita and contribute the most to climate change.

These differently scaled environmental burdens can overlap and create environmental injustices, wherein those who face the most hardship as the result of larger scale burdens, contribute the least to them. In polluted industrial cities, the poorest citizens tend to live downstream and downwind of the major polluters. Globally, those most at risk from climate change include the world's lowest income citizens, rural and urban, who are contributing least to global climate change.

Climate change is creating new environmental risks and exacerbating old ones, including the risks of inadequate water and sanitation provision. Urbanization is putting in place infrastructure that will not only contribute to or protect people from more local environment burdens, but will determine whether cities, and urbanization itself, contribute to climate change mitigation and adaptation. Where urban growth takes place will also influence how many people are living in risk-prone regions and localities.

Urbanization has been part of modern economic growth and is sometimes blamed for contributing to climate change and other global, environmental burdens associated with high consumption levels. It is important, however, to distinguish the effects of urbanization from those of economic growth, and to set both in the context of the prevailing political economy. When urbanization leads to higher productivity, it can be said

to be contributing to the larger ecological footprint that this productivity often facilitates. However, looking forward, this higher productivity is also likely to be a key ingredient in any successful attempt to reduce global environmental burdens without causing undue economic hardship.

Furthermore, excluding people from cities tends to exacerbate the impact of prevailing environmental problems. In low-income countries, addressing severe environmental health problems is generally cheaper in urban than in rural areas; and measures to put off low-income migrants, such as not providing services to rapidly growing low-income areas, is likely to prevent improvements in environmental health conditions for deprived urban residents and also for those forced to stay in rural areas Alternatively, when people in affluent countries move out from cities to low-density suburban or rural settlements, their environmental impact is likely to increase, particularly if they become more dependent on automobile transport.

Urbanization in Africa

Deborah Potts, King's College London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Urbanization in Africa has become somewhat differentiated from the processes experienced elsewhere, particularly in Asian countries. Global market forces caused some deindustrialization in sub-Saharan Africa and urban economies weakened in the last two decades of the twentieth century. Urban incomes declined in real terms, presenting major challenges to policy makers. In a range of countries, the rate of growth in levels of urbanization slowed as net in-migration rates fell as urban economic opportunities became less attractive. GDP growth rates have since strengthened largely due to natural resource-based developments. The impact of these on urbanization is very variable between and within countries.

Africa, south of the Sahara, has been profoundly rural throughout human history. In 2013, at the time of writing, this was no longer true for some countries – including Cameroon, Ghana, and South Africa – which had passed the significant tipping point whereby most people were residing in urban settlements. However, most large countries in the region are still mainly rural. Higher levels of urbanization tend to be found in the smaller nations with small populations. North African countries are different: all are mainly urban except Egypt but their economic and social history, embedded so firmly for millennia within the Mediterranean region, has been quite different from sub-Saharan Africa (see **Figure 1**).

Historical Background

Since it is such a vast continent, it is often misleading to generalize about phenomena in Africa. There is huge variation between the historical influences, which laid the basis for urban settlements, for example. North Africa has some of the world's oldest settlements, while those in central Southern Africa are some of the newest. Their locations reflected their roles in the societies which existed when they developed, and the mode of production of the moment. Consider the differences between cities such as Alexandria in Egypt, established by the Pharaohs, developed by Alexander the Great, and which served as Egypt's capital for a 1000 years until the Muslim conquest in the seventh century, and town like Lusaka, Zambia's capital, a small British colonial railway settlement that only became the capital city in 1935.

Many of the large towns of sub-Saharan Africa, including capital cities, were essentially established either to serve the needs of European colonizing powers in the late nineteenth or early twentieth century, or developed before formal colonies were established as a result of economic changes wrought by the rapid expansion of sea-borne European mercantilism from the end of the fifteenth century. Ports along the West and Central African coastlines often began in this way, from Saint Louis on the border of Senegal and Mauritania to Luanda and Lobito in Angola. In many cases, the primary stimulus for their establishment was the slave trade. By contrast, in West Africa historical, indigenous African urban settlements such as Timbuktou, Sokoto, Maiduguri, and Kumasi were in the interior, serving the commercial and political needs of various former great African empires and states such as the Bornu Empire, the Sokoto Caliphate, and the Asante Kingdom. Indigenous urban settlements also included the Yoruba agro-towns of the Oyo kingdom (Krapf-Askari, 1969). All major towns in these systems were involved to a greater or lesser extent in trans-Saharan trade with North African societies. Those in the Sahel reflect the influence of Islam, as do the cities of northern Africa. The advent of colonial administrative control and the creation of new countries with borders shaped entirely by European strategic interests at the end of the nineteenth century was often a devastating blow for these indigenous towns. Their political and economic roots were frequently transformed or destroyed either by outright conquest or the more insidious forces of economic geography as colonial administrations and companies wrenched the region's productive forces and urban systems away from their northern or inward-facing activities and refocused them on channeling exports of minerals and agricultural products to the ports and Europe. Some declined, others took on new roles in the colonial administration or commercial developments. In these cases, hybrid cities emerged with new, often racially segregated, colonial elements alongside the established indigenous towns (O'Connor, 1983): an example is Kano in northern Nigeria.

In southern and eastern Africa, with the exception of the coast, nearly all towns developed under European colonial or white settler administrations. Racial segregation was 'planned' into these towns, and African workers who migrated to them for work were discouraged from permanent settlement for decades. The further south you went, the more fiercely and effectively were such policies implemented, reflecting the racist sentiments and imperatives of the large numbers of white settlers in countries like South Africa, South-West Africa (today's Namibia), and Southern Rhodesia (now Zimbabwe). They culminated in apartheid policies in South Africa. Their primary aim was to limit the growth of a permanently settled black African urban population because that would inevitably create political forces which would undermine the white settler state. While these policies succeeded in reducing the rate of African urbanization for some decades, they could not stop it altogether. Eventually, in 1994, the inevitable came to pass and South Africa became a democratic state, but only after a bitter struggle against apartheid fought mainly in the African

Figure 1 Urbanization levels in Africa. Notes: where possible census data have been used to calculate urbanization levels. The uncertainties about some countries' levels are discussed in the text. UN-Habitat data from the State of African Cities 2010 have been used particularly for those countries where it is known the level is over 50%. Levels for small island states are represented by the color of the dot for the capital city. Sudan is now two states but it has not had separate censuses yet, so the prepartition state is shown.

residential areas (known as townships) of the larger cities. The legacy of this racist, colonial past in the built environment of contemporary cities in this part of Africa is still evident, and problematic for the development of more inclusive towns, although time and subsequent physical expansion in many eastern and central African towns means they are essentially now expressions of postcolonial urbanization. The towns on Africa's east coast, north of South Africa, were often established prior to European contacts and had been strongly influenced in their function and location by contacts with Asian and Arabic trade, including slavery. Where they survived, the Arabic influences are also apparent in their historic centers, as in Zanzibar.

The major exception in urban historical terms in East Africa is Ethiopia. First, it was not colonized for any significant period and, second, its capital city, Addis Ababa, was the last of a series of famously 'wandering capitals' (Horvath, 1969) and not established until 1886. As it developed under a feudal political economy, its morphology is exceptional with an extraordinary mixture of house types and social classes in its densely settled central areas. The contrast between this 'inclusive' city and the divided cities of South Africa is stark.

African Urbanization in a Globalizing World Economy

African towns are now mainly shaped by the economic forces of contemporary global capitalism. From about 1980 to the global financial crash of 2008, sub-Saharan African urbanization, perhaps more so than any other part of the world, was subject to the ideological fashion for neoliberal capitalism, with increasingly unregulated free market forces determining urban economies and the livelihoods of millions of urban residents. This was a significant departure from the

modernizing policies of the post independence era (usually from the 1960s), which in most African countries had sought, via government policies, to diversify national economies away from what was felt to be the dangerous and restrictive over-reliance on commodity exports inherited from European colonialism. Those policies had fostered infant industries and investments in woefully limited social and economic infrastructure, much of which created strong urbanizing tendencies. In this way, for a brief period, postcolonial Africa attempted the type of development strategy which typified the postwar period for developing countries. However, given the lateness of independence in the region, most countries had little time, often a decade or less, before the first oil crisis in the early 1970s changed the global economic context drastically. The second oil crisis in 1979 meant many African countries' debt became intractable at the same time as the profound western ideological shift toward neoliberal economic policies began to take effect.

As a result, to a greater extent than elsewhere, the main economic influences on sub-Saharan Africa's postcolonial urbanization have been increasingly unregulated market forces and a sharply reduced public sector role. Most countries in 1980 still had very small economies and, once heavily indebted, lacked the economic weight or political clout to temper the economic 'medicine' of neoliberal financial institutions, unless they were perceived to have some strategic significance in Cold War terms, such as Zaire (now the Democratic Republic of the Congo (DRC)). Donor conditionality ensured that most countries increasingly conformed to the tenets of neoliberal market reforms, with open economies, liberalized trade, uncontrolled currencies, and cutbacks in government expenditure. The impact on urban economies and the livelihoods of urban residents was more dramatic than elsewhere in the world largely because of three factors: first, most countries were still very poor and urban poverty had already begun to rise in the 1970s as governments became more indebted; second, welfare nets for urban residents scarcely existed; and third, as rules of comparative advantage came to determine what African countries could produce, many urban-located large-scale enterprises proved uncompetitive and national economies were pushed back toward dependence on primary commodity exports. Formal sector employment dwindled relative to the size of the general workforce in African towns and cities, and towns across sub-Saharan Africa informalized to a remarkable degree.

The Links between African Urban Economies and Livelihoods and the Built Environment of the City

The nature of economic activities shapes cities in many ways. It sets the parameters of urban workers' incomes, the city tax base, and the practicability of different policies to provide essential services such as housing, water, sanitation, and transport. A major constraint for African towns is that many struggle to be major forces of production within their countries, instead relying on trade and services for their economic base. Of fundamental importance has been Africa's inability to industrialize. In comparison to Asia, African towns have fared extremely poorly over the past few decades in the creation of steady, wage-paying jobs for unskilled and semiskilled workers in industrial enterprises. Millions of such jobs have been created in Asia, from South Korea to Cambodia, from Vietnam to China. Sub-Saharan African towns have been unable to compete for these jobs for a range of reasons. Their workforces tend to be considerably less well-educated. Urban infrastructure tends to be very poor. Electricity supplies are often irregular. National governments, constrained by donor conditionality and prevailing neoliberal ideology, have found it difficult to intervene and foster industrialization via tariff barriers, or by the myriad of other policies practiced in other countries to encourage manufacturing industry beyond the 'natural' limits of comparative advantage, such as making artificially cheap loans, electricity, or water available. The fact that African countries tend to remain among the world's poorest also constrains these sorts of interventions. Furthermore, as the center of global economic gravity has shifted toward Asia, simple geography enhances the competitiveness of countries in that region for any outsourcing of the cheaper end of supply chain activities. Thus cities in countries like Cambodia have, so far, benefited from industrial investments looking for cheaper labor forces than can be found in, say, China, rather than African cities. There has been some Chinese manufacturing investment in Africa, particularly in countries with large markets like Ethiopia and Egypt, and cheap labor is one factor (Xiaochen, 2012) but the numbers of jobs overall, as yet, remain extremely limited by comparison.

African urban economies have often actually deindustrialized. The structural adjustment programmes (SAPs) enforced by the World Bank in the 1980s and 1990s allowed imports of cheaper products, which led to many industries in African towns closing down or reducing output. In Zimbabwe, the manufacturing industry accounted for about a quarter of GDP at the end of the 1980s. SAPs were introduced in 1991 and by 1998 the share had fallen to 17% (Potts, 2010). The example of Nigeria is detailed in **Box 1**. Light manufacturing exports from sub-Saharan Africa comprised only 0.9% of the world total in 2008, a decline from 1.2% in 1980, and the African Competitiveness Report for 2011 stated that the conditions for heavy manufacturing are simply not met in most low- and middle-income sub-Saharan African countries. It is rather sobering to realize that in 2008 Vietnam exported more light manufacturing products than all of sub-Saharan Africa, including South Africa (World Economic Forum et al., 2011).

The problem for African urban livelihoods is that while manufacturing industries are far from the only source of formal employment and prosperity in cities in developing countries, they create very positive multiplier effects and growth in many other sectors such as formal financial and commercial services is greatly enhanced. The regular wages from such jobs create virtuous circles, stimulating the housing, retail, and leisure sectors. These incomes can also make it possible to provide crucial services and recover their costs. Yet in many African urban settlements, this is a challenge simply because even basic infrastructure and housing, provided by formal, legal channels, is unaffordable to the majority.

Contemporary African urbanization needs to be understood in relation to these underlying economic constraints. It is generally claimed that in most sub-Saharan African towns most people work in informal sector jobs, and that the majority of

Box 1

It is estimated that 80% of Nigeria's textile factories have closed (Green and Macnamara, 2008; citing Alden) and 250 000 urban textile workers have lost their jobs because of foreign imports – equivalent to just under a quarter of the manufacturing workforce in the late 2000s. In the north of the country, textile manufacturing was the only urban-based industrial sector of any significance, but much has now closed, exacerbating already very high levels of urban poverty (Burgis, 2009). The southeast of Nigeria has a far more broadly based and dynamic tradition of domestic manufacturing. This includes the town of Aba, famed for its local small- and medium-scale (and sometimes handmade) shoes and clothes industries. Many of these used machinery imported during the 1970s and 1980s when the Nigerian currency was strong due to the oil boom. However, in recent years these have also been very badly affected by the 'flood of cheap imports that has accompanied China's strengthening ties with the continent' (Mahtani, 2007). It is estimated that by 2007 half or more of the market for Aba's shoes had been captured by East Asian imports. Similar problems led to many industries closing in nearby Nnewi, which was known for its motor parts trade (Financial Times, 2007). Attempts by the Nigerian government to reintroduce protection for domestic textile manufacturing have been widely circumvented by importers who recertificate Chinese textiles as locally made (Burgis, 2009). On the other hand, clothes manufacturers who did depend on certain types of high-quality imported fabrics have suffered as these have become difficult to obtain, except through smuggling (Mahtani, 2007). Nigeria has, like many other African countries, tried to encourage foreign investment in manufacturing by setting up Free Trade Zones. There is one in Calabar, also in Nigeria's southeast. However, domestic manufacturers outside the zone argue that this also causes them to suffer from unfair competition from within their own country (Beattie, 2007).

new jobs are found in this sector too. As reliable and comparable employment data in different towns may be hard to find, it is difficult to be precise. For most African urban residents, however, their livelihoods, the places where they live, and the things that they buy can be characterized as informal. While there is much disagreement about where formality ends and informality begins, it is usually agreed that typical urban informal jobs include self-employment as petty traders, selling everything from vegetables to cheap clothes (now often imported from Asia) to charcoal to drinking water in sachets, as well as small-scale producers (e.g., of furniture or metal products, often recycled), provision of cooked food and local beer production and sale, and a host of services such as hairdressing, motorbike taxis, house construction, car repairs, tutoring, or tailoring. Other typical features are that the activities do not conform to official regulations about, for example, business premises or health and safety conditions, rarely maintain accounts, and pay no income tax. Family members may work together in some enterprises, although some may not get paid. The production and incomes generated by informal sector work are also very imperfectly captured by government statistics, if at all.

Urban informality has its pros and cons. In much of Africa, economic safety nets such as pensions or child benefits are nonexistent or very inadequate – although some countries in southern Africa, and Kenya and Senegal have been gradually introducing these. Therefore, most adults must work if they are to survive and, if the formal sector cannot provide jobs, self-employment is the answer. The informal sector has a great capacity for 'involution' whereby many people produce and/or trade items that could be more 'efficiently' produced and distributed by far fewer in the formal sector (Armstrong and Mcgee, 1968). This ability to absorb the urban workforce in Africa when formal job growth is outpaced by population growth is beneficial. For decades, many reports on urban Africa argued that urban unemployment rates were very high but these did not properly account for the informal sector. It is now recognized by the African Development Bank (2012) that, in contrast to previous assumptions, poorer African countries tend to have *lower* urban unemployment rates. Another advantage is that 'informal' goods are sometimes cheaper than formal sector products because labor is cheap, or the products are lower quality or use recycled materials. Even when informal traders' prices are more expensive than formal sector outlets, if there is a market for the goods evidently the producers and sellers provide for a need – classic examples being the subdivision of luxury items into units that poor people can sometimes afford (half a loaf; one cigarette) or are bringing goods (e.g., groceries brought from wholesale formal outlets) to locations where the formal sector cannot or will not reach, probably because profit rates would be too low or formal outlets are not facilitated by the state.

The informal sector has negative aspects too. It is characterized by very low incomes, which are also often very irregular. This makes people's lives very difficult and vulnerable. The lower unemployment rates in poor cities are associated with a desperate survivalist need to work and earn even tiny incomes in highly insecure social and economic environments. In these circumstances, low unemployment can be an indicator of poverty rather than opportunity. Research for the African Development Bank (2012) found that "the unemployed are less likely to suffer from poverty than many self-employed or underemployed" (p. 102), the reason being that unemployment may only be possible if an individual has access to some other source of income or support. Furthermore, African governments, both at the national and city scale, have been highly ambivalent in their attitudes toward the informal sector. They sway back and forth between regarding it as deeply negative and a hindrance to development, and seeing it as a partial solution to unemployment and a starting point for new entrepreneurs. Since the 1970s, many official policies include at least some element of supporting SMMEs (Small, Medium, and Micro-Enterprises), and this usually embraces the more profitable informal enterprises. Partly, and understandably, the incentive for governments is to bring such economic activities within the official tax net, thus strengthening the city's revenues. However, the intractable obstacle for this worthy approach is that nearly all surveys of African urban informality find that the majority of workers are self-employed, usually in trade. Many are women who may combine their flexible work patterns with household responsibilities, including child care. Their characteristics do not fit the SMME projects.

Official attitudes unfortunately frequently veer off into the punitive, sometimes in drastic ways. City laws (often inherited from colonial governments) often deem the 'informal' 'illegal.' For most of the time informality is tolerated, otherwise African cities would not work (in both senses of the word). And government officials and politicians are often deriving some of their own incomes from the so-called informal activities. For example, the renting of rooms in one of Nairobi's large slums,

Kibera, provides large profits for some people in the government. Nonetheless, urban planners are rarely in favor of the urban informal sector because, almost by definition, it is unplanned and flouts regulations. The sector's 'image' is also problematic. Governments often want their capital cities, in particular, to appear 'modern' and 'planned.' Downtown traders in particular undermine that image and are periodically discouraged or even banned. The police often harass informal traders, sometimes with a view to obtaining bribes, or steal goods under the pretence that fines are being levied for breaking laws. An infamous example of a government campaign against urban informality occurred in Zimbabwe in 2005, when virtually every informal worker and enterprise was banned from operating, and all the unplanned houses were demolished in Operation Murambatsvina ('Drive out the Trash'). All this adds to the vulnerability of informal sector workers, and undermines their already low incomes.

The typically low incomes also mean many African urban residents can neither afford reasonable urban housing nor 'formal' sector provision of essential services like water, sanitation, and electricity. At another level, it also means that there is a significant proportion of Africa's urban residents for whom it is almost impossible to provide these services via the formal sector on a cost recovery basis, let alone through any large-scale profit-making private venture. As a result, extremely high proportions of urban dwellers live in unplanned housing, with very poor services. Sanitation conditions can be very dangerous for health. While everyone does have access to water or they could not survive, it may have to be purchased in small quantities from local vendors, or obtained illegally by tapping into piped supplies, or taken from local wells, which may be contaminated. If electricity is available it is often too expensive for ordinary urban residents: again tapping illegally into nearby power supplies may solve the issue although this is dangerous. Many use charcoal or kerosene.

Highly innovative, often community-based, approaches can make very positive improvements in these areas (Satterthwaite and D'Cruz, 2005). For example, the now global organization, Shack Dwellers International, has worked with many low-income residents in African cities to help them plan how their housing conditions could be improved and then negotiate with city authorities to implement their solutions. City officials may welcome practical solutions to what sometimes seem impossible urban conditions. However, if city politicians are highly authoritarian and antagonistic toward informality, this may not work as the approach does depend on a degree of flexibility about urban planning rules, which must often be relaxed, and a reasonably benign government. Negotiating for some form of tenure security so that residents of unplanned settlements do not exist under threat of eviction is often a starting point for other improvements to occur in urban living conditions. One feature of many African cities, except for those furthest south where major towns were mainly built on land alienated by white settlers from indigenous people, is that large numbers of low-income residential areas occupy land which was obtained via various forms of customary tenure. This may make their residents more secure than those squatting on private or public land held under capitalist property rights. It also tends to be much cheaper. However, unless such settlements are recognized by the local government, they may find it difficult to obtain urban services. What forms of tenure are acceptable and effective for low-income residential areas is one of the most significant debates about African urbanization. UN-Habitat, the global agency, which focuses on human settlements and which is based in Nairobi in Kenya, took this as one of the main themes of its 2010 *State of African Cities* report (UN-Habitat, 2010).

Urban Population Growth and Urbanization Levels

African countries tend to have high population growth rates because birth rates remain high. Even in southern and North African countries, where they are lowest, the rates tend to be higher than in most of South Asia and much higher than anywhere else in the Global South. In the rest of Africa they are much higher still, usually over 30 per 1000 and sometimes more than 40. Natural increase rates also tend to be high in African towns – their rate of growth simply from annual increments to their populations from births minus deaths is very high relative to other urban areas in the world. For these reasons, African urban populations tend to be growing faster than those in Asia or Latin America. This is often taken to mean that Africa is the world's fastest urbanizing region, but this is a mistake. The rate at which a country urbanizes – how fast its population is shifting from being rural to urban – depends not on absolute growth rates but the gap between urban and national growth rates. Current data suggest that Asia has been urbanizing faster in the past 10–20 years.

The reason is that Asian urban economies have been stronger than those in Africa and this has encouraged more long-term in-migration to Asian towns. The rate at which African populations were shifting from being rural to urban slowed in many countries toward the end of the twentieth century due to the weakening of urban economies. In the 1960s and 1970s, urban growth rates had often been phenomenal: many large towns like Nairobi, Lusaka, and Abidjan grew at annual rates of over 10% for about a decade, largely due to rural–urban migration. However, the falls in urban incomes in real terms during SAPs squeezed the gap between rural and urban incomes, which is a key driver of rural–urban migration. This phenomenon was charted by economists for a range of African countries in a book entitled *Africa Misunderstood, or whatever happened to the rural-urban income gap*? (Jamal and Weeks, 1993). As the gap reduced, net in-migration to urban areas in some countries fell. This did not necessarily mean that rural–urban migration rates fell steeply, though there is evidence that this happened in some countries. Many migrants still came to towns for cash wages and in the hope of better incomes. However, urban livelihoods had become very vulnerable, and lack of work and low incomes meant that many people found they could not afford to stay in towns and so urban–rural migration rates rose. In sub-Saharan Africa, rural–urban migrants may still maintain access to land through indigenous tenure systems and this facilitates circular migration between rural and urban areas. The pattern had often been encouraged or, in southern Africa, enforced by colonial regimes. It continued in the postcolonial years although with many adaptations: families came to join migrant household heads in towns and length of stay in town increased

significantly. Sex ratios in towns swiftly normalized in the 1960s and 1970s. Nonetheless, rural–urban linkages were still strong and older migrants 'retiring' back to rural areas remained quite common. When the rural–urban income gap narrowed sharply, these linkages and migration patterns strengthened again, and the annual net addition to urban populations from migration fell.

For Africa as a whole, it has been estimated that the contribution of net in-migration to urban growth was about 40% in the 1960s and 1970s, but fell to only 25% in the 1980s (Chen et al., 1998). In Tanzania in 2001–02, the contribution has been calculated to have been only 17% with most growth coming from natural increase and the reclassification of rural populations. Circular migration was significant – rural–urban and urban–rural migration flows totaled about 389 000 people – but net in-migration to urban centers was only around 44 000, 0.6% of the urban population. In addition, about 190 000 moved between urban centers (Muzzini and Lindeboom, 2008).

The first country where these impacts were recorded in urbanization levels was Zambia. In the 1970s and 1980s, it experienced a particularly negative set of economic and political forces: the oil price rises leading to debt; a massive fall in the prices of its key export, copper; and violent conflict in the region surrounding it, which proved especially costly since it was landlocked. In 1990, Zambia's census showed that it had counterurbanized in the 1980s: the urban share of the population had fallen from 40% to 38%. Net migration rates shifted to being urban–rural and several mainly rural provinces experienced strong in-migration. Since then a few other countries also experienced periods of counterurbanization: Cote d'Ivoire, Mali, the Central African Republic, and Zimbabwe. Zambia continued to counterurbanize in the 1990s but reurbanized from 2000 to 2010, although the urban share in 2010 was still less than it had been 30 years earlier. Mali's urbanization levels have also increased again. More commonly, large sub-Saharan African countries experienced a marked slowing in the rate of urbanization. Many censuses toward the end of the 1990s and in the twenty-first century found that the increase in the urban proportion had been under 2%, and in some cases 1% or less, over intercensal periods, which were often much longer than 10 years. Benin, Ethiopia, Malawi, Mauritania, Mozambique, Niger, Senegal, Sudan, Togo, and Uganda are in this category. Analysis combining the limited available data from Nigeria's 2006 census and from Africapolis – a French research project using aerial photographs to estimate town populations – suggests that Nigeria should also be included (Potts, 2012). Africapolis reports even argue that urbanization levels across much of West Africa have been overestimated by UN agencies and the World Bank (Africapolis Team, 2008). This is largely due to long gaps between censuses, which had led to urban populations being estimated from projections based on earlier, more rapid, growth. Two of sub-Saharan Africa's largest countries, the Democratic Republic of the Congo and Angola, have not had any census for decades so their urban populations can still only be estimated. The combination of this past tendency to overestimate urbanization levels and the recent census data indicating lower levels can cause confusion. The data set on urbanization levels held by UN-Habitat, the main global agency focused on urban settlements, in 2013 suggested that urbanization levels in 17 African countries had declined between 2000 and 2010. At the same time, the same agency strongly promotes the view that Africa is urbanizing rapidly. The contradictions arise because the overgenerous estimates for 2000 have not been corrected. Yet, even the downwardly revised 2010 estimates are too high for some countries according to their recent censuses; for example, Chad, Madagascar, Liberia, Malawi, Mozambique, and Zimbabwe.

In addition to the slowing of urbanization attributable to changes in migration patterns to large towns, for some African countries reported urbanization levels may also overestimate how many people are living in truly urban settlements and give a false impression of the extent to which a country's workforce has shifted away from rural economic activities. Urbanization levels are often used as a proxy for economic development on the assumption that they reflect important sectoral changes in the constitution of a country's GDP and employment. Yet many African countries not only define rather small settlements as urban, but also do this without regard to whether their residents are still working in agriculture. Were the urban settlement definitions used in India, which factor in economic activity patterns, applied in such countries, their urbanization levels would fall sharply.

This definitional issue is of significance for two of East Africa's major countries, Kenya and Tanzania. Both are portrayed by their governments and agencies like UN-Habitat and the World Bank as urbanizing rapidly. The capital cities of Nairobi and Dar es Salaam have grown fast for decades. Nonetheless in both the level of real urbanization is lower than generally claimed. In Tanzania, there is no clear definition of what is urban. The census figures may include not only the main town, but also periurban wards, which are designated 'urban,' and even mixed rural–urban wards where much or part of the population is definitely rural. There is no doubt that this led to a general overestimation of real urban population growth (Holm, 1992). Furthermore, one third of those employed in the urban population of Tanzania (including large towns) was recorded as working in agricultural activities in 2002. In small towns and townships, the vast majority (67%) were working in agriculture (Muzzini and Lindeboom, 2008). For these reasons, it seems certain that a functional urbanization level for the country in 2002 was less than the 23% recorded in the census. Similarly, in Kenya's recent census of the urban population has included both 'core' urban areas and 'periurban' areas. Often the latter include many rural people and for some urban areas, it is evident that the vast majority of the population are farmers. Kenya's 2009 census recorded its urbanization level as 30% but the core urban population was only 23% of the national total.

Africa continues to urbanize but the various factors discussed show that the rate at which this is occurring has slowed and that the level of urbanization is less high than often assumed. The primary reasons are economic. Distinguishing between rural and urban populations is important if urbanization is being used as an indicator of certain types of economic development and change. However, from the perspective of evaluating the livelihoods of most people in sub-Saharan Africa, the distinctions may be less useful. One problematic aspect is that in many urban areas, including some very large cities like

Kinshasa, the capital of the Democratic Republic of the Congo, many residents who work in urban-based activities also derive some or occasionally most of their food from urban agriculture. This was encouraged by the fall in real urban incomes from the 1980s, which led to poor households spending very high proportions of their incomes on food. In addition, it is common for low-income urban households to maintain linkages with rural kin and vice versa. These linkages include social and economic aspects such as remittances of cash and goods, food produced in rural areas being brought to towns, and visits and circular migration between households at both ends of the spectrum. The composition of connected households can shift over time as rural versus urban opportunities and needs change. In this way, the rural–urban divide is blurred. This adds a further layer to discussions about African urbanization.

Africa's Urban Prospects

From about 2003, many sub-Saharan African economies experienced a surge in growth rates of GDP after a period of up to two decades of stagnation and decline. Some countries, like Angola, have been among the world's fastest growing economies. The primary reason has been the growth in demand for a range of natural resources from Asian countries, particularly China, to fuel their industrialization and infrastructural development. Africa is rich in natural resources and there have also been many new mineral and energy finds. Offshore oil and gas finds of global significance are shaping new economic directions in both West and East African countries, which previously were not involved in these sectors, such as Ghana, Tanzania, and Mozambique. High gold, copper, and other metal prices encouraged new large-scale corporate investments in many countries, including these three and Zambia. The proposed development of extraordinary iron ore reserves in and near Guinea – at least 50 billion tonnes – by international investors and the IFC of the World Bank has been promoted as possibly SSA's 'largest industrial investment project ever' (AIOG, 2012). The ending of conflicts in southern African countries as white minority rule and the Cold War ended has also helped economies to reestablish growth.

These economic changes are having urbanizing effects. For example, ports are creating new jobs and attracting new migrants, as with Tema and Sekondi-Takoradi in Ghana, both of which grew much faster from 2000 to 2010 than the capital, Accra. In Nigeria, oil cities like Port Harcourt and Warri in the southeast have similarly experienced higher population growth than most of Nigeria's other towns, including Lagos, the commercial capital. Kumasi, in Ghana's interior, has been growing at about 5.5% annually between 1984 and 2010 and its population now rivals that of Accra, the capital city. It has always had a key marketing role in the local economy and functions as a central place for a hinterland with strong exports of cocoa, gold, and hardwood. Arusha in Tanzania also serves a productive commercial agricultural hinterland and has similarly experienced very high rates of population growth, exceeding those of the capital city of Dar es Salaam in the 1990s. In addition, it has the offices of the regional grouping, the East African Community, as well as being a central node for tourists, often flying into Nairobi from Europe, since it is well placed for access to some of the world's best wildlife parks. Small-scale artisanal gold mining in Tanzania has had vigorous urbanizing impacts in small towns in Tanzania (Bryceson and Jønsson, 2010). Tete, in Mozambique, was hard hit by that country's civil war in the 1980s but became one of the fastest-growing large towns in the country with new foreign investment in its huge coal reserves.

The evidence suggests that, in sub-Saharan Africa, natural resource-based economic stimuli are increasingly the cause of urban population growth where it is significantly in excess of that derived from natural increase or the reclassification of small settlements. This is logical since this is the main source of national economic growth. This is a direct contrast to Asian urbanization, which is being driven by significant industrialization with millions of jobs created within urban settlements. In Africa, many of the new jobs created by recent economic changes are not urban-located, such as those in offshore oil and gas, timber, and agricultural developments. Large-scale mining of commodities like copper and coal, on the other hand, is more often directly associated with the creation of major towns, as in Zambia and the DRC, for example. The largest conurbation in Africa in Gauteng Province in South Africa, centered on Johannesburg, has its origins in gold mining. Nonetheless, mineral developments can be associated with the creation of enclave economies, with relatively few jobs in very concentrated locations, and a lack of forward and backward economic linkages stimulating other urban employment-creating enterprises. Africa has experienced this before during the colonial and early postcolonial periods. The patterns are illustrated by Zambia's experience: it began to reurbanize after 2000, after 20 years of counterurbanization, as copper prices surged and the output of its copper mines in the Copperbelt towns increased. Yet four of the five largest of these towns grew more slowly than the national population from 2000 to 2010; the most vigorous growth was experienced in the capital city, Lusaka, which grew at nearly 5% per year.

The future of African urban economies and internal migration trends will partly depend on the extent to which governments are able and willing to translate increased income from natural resource production into diversified and specialized urban-based formal employment opportunities. The multiplier effects of such employment would foster further sustainable urbanization with the development of more viable urban livelihoods. Yet the history of shocking inequality in incomes and the limited spatial spread of the benefits of GDP generated in oil-rich countries like Angola, Nigeria, Equatorial Guinea, and Congo does not provide a positive precedent. African governments have also struggled to negotiate reasonable deals with the world's extremely powerful transnational mining companies; in some cases, they have been poorly advised by international financial institutions and have reaped far less from mineral investments than countries like Chile (Larmer and Fraser, 2010). If strong demand for natural commodities continues, however, their bargaining power increases and there are signs that African states are becoming more assertive about the nature of mineral contracts. A good example here is Botswana, which has experienced very positive economic growth for decades driven by its valuable diamonds, which are mined in collaboration with De Beers. The government has managed to derive reasonable levels of revenue from

the diamonds, although this is partly because the sheer scale of its resources gave it a strong bargaining hand. Nonetheless, it is now more than 50% urbanized with some of the urbanization occurring as the occupational structure of its large, traditional agro-villages shifted from agriculture-based to a range of more diversified and specialized urban-type work as the national economy grew and developed. The government has made very specific efforts to diversify, in very difficult circumstances. The national population is small, only 1.9 million in 2011, and the regional economic powerhouse of South Africa across the border provides tough competition. Nonetheless, Botswana counts among the most successful exporters of light manufactures in SSA (World Economic Forum et al., 2011). Small island states like Mauritius have been more successful in industrializing and urbanizing, and Lesotho has developed a textile sector. But these countries have tiny populations and are not typical of sub-Saharan African nations; furthermore, their seeming success is often due to special trade treatment by the United States and EU, such as the USA's African Growth and Opportunity Act (AGOA), without which their manufactured exports would be uncompetitive.

The classic linear development models, which assumed that economic development, urbanization, and industrialization progressed together, are challenged by Africa's experience. Urbanization has slowed, stalled, and even occasionally reversed at times and the same is true of industrialization. The natural resource-driven economic growth pattern may not dominate in the long term, but it does impose constraints on urban livelihoods and economies. Where vigorous urbanization is occurring currently, it tends to be associated less with production based in towns and more with trade and services linked to primary commodity sectors. The extent to which this can be translated into better and more dependable incomes for Africa's urban dwellers is still uncertain.

Abstract

This article on China's urbanization examines the main drivers behind China's urban transformation, its impact on the society, and how the impact is unevenly spread across populations and geography. It begins with a brief historical summary of China's urbanization focusing on the post-Liberation period, that is 1949 onward, and moves on to discuss some of the major factors that have contributed to people's migration and urban physical expansion. Three key characteristics are paid particular attention: (1) industrial production and uneven development; (2) land-based accumulation; (3) local state building and state entrepreneurialism. The article further examines some of the important sociospatial outcomes and challenges that China's urbanization poses.

Introduction

Viewed from a demographic perspective, urbanization refers to the growth of the urban share of the national population. This growth can be achieved by a number of ways: the natural growth of the existing urban population, the migration of rural residents to urban areas, the physical expansion of extant urban administrative boundaries, and the emergence of new towns as beachheads of further urban growth in neighboring areas. For China, while the fertility control through the implementation of the One Child Policy since 1979 has been a constraint upon urban population growth to some extent, migration as well as the territorial expansion of urban areas has substantially increased the rate of urbanization in recent decades (Song and Timberlake, 1996; Hsing, 2010). While China's urbanization rate reached just under 20% in the late 1970s at the time of embarking on its economic reforms, China's 2010 Population Census revealed that almost 50% of its national population was now classified as urban. The subsequent year 2011 was the landmark point for China, seeing the majority of the national population marked as urban for the first time in its history. The United Nations Population Division has predicted that China will add another 10% by 2020 (United Nations Population Division, 2012: Table A.2). China's new leadership from 2012 has also expressed explicitly their eagerness to make sure China's urbanization reaches 60% by 2020, which will help boost the country's consumption basis to create domestic demand and therefore sustain economic development in the next decade or so (Shanghai Daily, 2013; see also Chan, 2014). While the reliability of these official statistics may be subject to scrutiny and proper interpretation (Brenner and Schmid, 2014), it is important to understand what the state aspiration of urbanization aims to achieve.

The recent emphasis on 'urban' is not a surprise. Increasingly, an urban way of life has been regarded as 'modern' and 'civilized' while the rural has been associated with backwardness (Anagnost, 2004). The theme of the Shanghai World Expo 2010 written in English was 'Better City, Better Life.' To many spectators and visitors from outside China, the English slogan was reflecting a common sense understanding. Improved urban conditions including infrastructure, services, and environment would result in a better life for citizens. However, the Chinese version of the Shanghai World Expo meant entirely something else. In Chinese, the slogan reads '*Chengshi, Rang Shenghuo Geng Meihao*,' which can be literally translated as 'City makes life happier.' The emphasis was no longer on a 'better city' but on the 'city' itself. Constructing "urbanization as a political and ideological project" (see Shin, 2014a), the Chinese Party State was sending out a clear signal to its domestic population that an urban way of living was the way forward for the nation.

This article on China's urbanization examines the main drivers behind China's urban transformation, its impact on the society, and how the impact is unevenly spread across populations and geography. It begins with a brief historical summary of China's urbanization focusing on the post-Liberation period, that is 1949 onward, and moves on to discuss some of the major factors that have contributed to people's migration and urban physical expansion. Industrial production and uneven development, land-based accumulation, and local state building are the three theses that are given particular attention.

Urbanization Trend

China's rates of urbanization have been very much influenced and shaped by the national policies that alternated between strict control and relaxation (Song and Timberlake, 1996). Since the Liberation in 1949, China has gone through dramatic changes in terms of urbanization and industrialization. The 10-year period between 1950 and 1960 was devoted to raising the industrial output through the implementation of the first Five-Year Plan (1953–57) and the political campaign known as the Great Leap Forward, which resulted in high rates of urban in-migration. The following 5 years (1961–65) were marked by the sharp decline of urban population, which resulted from the return of migrants to their origin places in order to supplement labor shortage in rural areas due to the nationwide famine at the time (Chan, 1994). It was this period that witnessed the strict control of the grain ration distribution in cities and the tightening of population move through the implementation of the household registration system known as *hukou* in Chinese. The 1960s and the 1970s also saw a major sociopolitical

uprooting due to the reign of the Cultural Revolution that lasted almost a decade. Some of the most notorious campaigns and policies exercised in this period were resettlement campaigns, known as '*shangshan xiaxiang*' (up to the mountain and down to the villages) and '*xiafang*' (sending down). These sent hundreds of thousands of urban cadres, youths, and intellectuals to the countryside, and the number of these youths reached about 20 million (Naughton, 1995; Chan, 1994). A famous statement by Mao Zedong may express one of his main concerns during this period: '*Chengshi taidale, buhao*' (It is no good if cities are too big). Based on the apparent restraints of urban growth in the 1960s and 1970s, Barry Naughton states that economic planners in China "consistently made choices about the role and function of cities that tended to undervalue the contribution of cities" (Naughton, 1995: p. 61). On the one hand, the stagnant growth of urban areas during Maoist era has been evaluated by many scholars as a result of strong antiurban bias. However, it must be reminded that rather than ideological antiurban and prorural bias of the Chinese leadership, it was the strong motivation to drive industrialization for maximum accumulation that resulted in the urban retreat during the planned economy period (Kirkby, 1985).

China's economic reform since the death of Mao Zedong in 1976 has brought profound changes to urban life in China. Cities and towns, which had undergone a long period of hibernation during the period of Cultural Revolution that lasted about a decade since 1966, have been given the impetus to thrive again under the reform experiments that steer the nation to follow the path of so-called 'socialist market economy.' After a somewhat hibernating status of 'zero urban growth' during the 1960s and 1970s that saw no real growth of urbanization rate, China's urban share of its national population reached 32% in 1997, reflecting the rapid expansion of urban areas and high levels of urban in-migration lured by the new business and employment opportunities. It is however necessary to highlight the fact that the initial emphasis of economic reforms on the growth of township and village enterprises (TVEs) absorbed a substantial number of rural reserve labor, facilitating the transformation of rural farmers into industrial workers, and in doing so, achieving an economic expansion through what can be termed as 'urbanization from below' (Ma and Fan, 1994). From the mid-1990s, these TVEs gave way to large enterprises and foreign firms, which were increasingly concentrated in cities of the eastern and coastal provinces.

'Urban' as the Unit of Accumulation

From the early 1990s, after a brief spell of stagnation immediately after the Tian'anmen uprising, Deng Xiaoping's Southern Tour reignited China's drive for the economic reform. This time, its focus was more on prioritizing the eastern coastal region and special economic zones for resource concentration including the attraction of foreign direct investments and rural surplus labor for low production costs. These measures were epitomized in the widely publicized policy of 'Get Rich First,' which hoped for the eventual trickle-down of eastern coastal region's economic success to its hinterlands. The core and distinctive nature of China's urbanization during this period could be the rise of the 'urban' as the unit of accumulation. Three key characteristics are examined here: (1) industrial production and uneven development; (2) land-based accumulation; and (3) local state building and state entrepreneurialism.

Rise of Industrial Production and Uneven Development

Through the official endorsement of promoting a 'socialist market economy' by the Chinese Communist Party (CCP) in 1992, a full economic reform thrust was put in place, and major cities in the eastern coastal region received various preferential treatments to lead China to become the 'factory of the world.' While the exogenous factors of foreign direct investments and the formation of the global value chains have all facilitated China's transformation, the core domestic thrust in relation to urbanization could be the production and exploitation of the country's cheap labor force (Buck, 2007). This was facilitated by the household responsibility system in People's Communes in rural areas, which not only increased the agricultural productivity but also freed farmers from being tied to the collective commune system. This accompanied decollectivization, which allowed household members to engage in nonfarming activities as long as they fulfilled their obligation to the village collectives in terms of meeting the grain quota imposed upon each household (Zou, 2003). The 'Scissors' gap' between the agricultural and industrial products was abolished, and the control of household and employment registration had been considerably lessened throughout the 1990s, prompting the influx of migrants into cities. The production of cheap labor force is further aided by the household registration system that prevents migrant workers and their families from accessing full services in cities, resulting in what Kam Wing Chan (2014) refers to as *hukou*-based urbanization. China's rise as the factory of the world was also facilitated by the rapid development of the private sector and the restructuring of the state sector. Industrial outputs increased to an unprecedented level. The scale of foreign direct investment escalated exponentially, helping China to address its earlier resource constraints for financing investment in fixed assets. The FDIs largely focused on eastern coastal provinces such as Guangdong and Zhejiang, which saw a number of special economic zones emerging to accommodate production facilities for goods manufacturing for overseas market.

The economic reform and the prioritization of selected provinces and cities have resulted in uneven development with aggravating regional disparities, which became particularly prominent in the 1990s and early 2000s (Dunford and Li, 2010). Intraregional disparities have shown some signs of improvement over the years especially since the mid-2000s, but interregional disparities are yet to exhibit amelioration (Kanbur and Zhang, 2005). Such aggravation of regional disparities has led to the state implementation of regional policies that aim to redirecting resources to poorer regions. One of such policies includes the 'Go West' policy that aimed at diverting resources for investment in central and western regions (Tian, 2004). The attention of the central state to poorer and less-performing regions and provinces also owes its greater awareness of the need to boost the domestic consumption in order for the economy to sustain its current growth momentum. Some critics have noted China's vast territorial size as a safeguard for

China's interaction with the world economy on its own terms, and for the country's economy to take the advantage of the economy of scale (see for instance Liew, 2005). The expansion toward the western region in this regard has a great significance in terms of sustaining economic development as well as addressing political needs of addressing regional disparities (Shin, 2012). In this regard, cities such as Chongqing have grown to become a major regional hub, serving the domestic market in particular. With the increase in labor costs in eastern coastal provinces such as Guangdong, factories are also migrating further inland, relocating themselves to inland places that offer more preferential conditions in terms of lower wages and incentives for attracting these firms. These efforts by inland cities and provinces may involve the surge of state-led investments in fixed assets to provide the required infrastructure and facilities, reproducing in this process the speculative urbanization that characterized the cities in eastern coastal provinces (Shin, 2014a).

Land-Based Accumulation

Urbanization entails urban population increase but it also gets facilitated by the horizontal expansion of cities. In China, this equates to the territorial expansion that brings more land resources under the control of urban governments. For critics such as You-tien Hsing (2010), urbanization is synonymous with local state's territorial expansion, the process of which is summarized as 'urbanization of the local state':

> Local state leaders seek to legitimize themselves as urban promoters and builders, and urban agendas dominate local development policy, while local politics predominantly revolves around farmland conversion and industrial or commercial development projects. Urban construction has therefore expanded from an accumulation project to a territorial project of local state building. Urban modernity, now captures the political imagination of local state leaders. I call this dynamic the 'urbanization of the local state.'
>
> Hsing, 2010: p. 6

The control of urban land resources has become vital for Chinese cities' development, as the land reserves are the major sources of financing investments. Chinese local governments are known for their pursuit of land-based revenues, a practice that has gained importance throughout the 2000s in particular along with increased land commodification (Lin et al., 2014). With the reform of taxation system and decentralization, local governments are to retain a certain share of budgetary revenues, while extrabudgetary revenues raised locally are kept in the hands of local governments without having to be transferred to the central government. Land-related revenues such as land use premium and administrative fees upon land-use transaction constitute a substantial share of extrabudgetary revenues. Land-related revenues may also include loans borrowed by local government investment arms with the use of land as collateral (Ding, 2005). It is estimated that "These loans plus the revenue generated from conveyance fees accounted for 40 to 50 percent of the Hangzhou municipal government budget in 2002. In turn these revenues were used to fund more than two-thirds of the city's investments in infrastructure and urban services" (Ding, 2005). A recent study on Guangzhou suggests that the municipality's land conveyance income accounted for "about 20–25% of the total fiscal revenue" (Lin et al., 2014: p. 13) in the 2000s and "contributed 40–60% of the total urban fixed capital construction fund" (Lin et al., 2014: p. 14). China's dualist structure of land-ownership places the ownership of urban lands in the hands of the state (hence state-ownership of urban lands), while rural lands are owned by rural collectives. This provides monopoly control of land resources for local governments as *de facto* landlords (Shin, 2009), whose power of land administration has been delegated by the central government.

The utilization of land resources therefore becomes an important avenue of revenue maximization for local governments that strive to address the need of development, especially in the context of China's macroeconomic growth that depends heavily on investment in fixed assets (Shin, 2014a: pp. 505–507). The utilization of land resources may happen in four ways. First, urban governments may strive to gain their control over existing urban space that used to be occupied and controlled by what You-tien Hsing (2010) referred to as 'socialist landmasters,' that is, government institutions, state-owned enterprises, and militaries, which often make claims on the use rights of lands they occupied for years. They would do so in order to generate land revenues for their own benefits. Second, rural lands that used to lie outside the urban government control are subject to reclassification as urban lands through administrative boundary adjustments so that rural counties merge with neighboring municipalities. Third, the designation of development zones in rural counties bring greater opportunities for urban governments to raise more land-related revenues, as the strategic insertion of excluded landscapes boost the exchange value of land use rights (Wu and Phelps, 2011). Fourth and finally, existing urban spaces may be subject to revalorization through redevelopment in order to put them into a higher and better use (Shin, 2009). This process will involve expropriation of various fragmented property rights as well as the sorting of existing residents and businesses.

Local State Building and State Entrepreneurialism

China's urbanization therefore can be understood as the territorial consolidation of the power in the hands of urban governments. However, the pursuit of economic gains extends beyond land-related revenues. The rise of Chinese local states has been accompanied by their greater power to gain control on regulating local development initiatives (e.g., urban planning and land administration). The rising importance of land as commodity in financing local development has also led to the transformation of land governance into an entrepreneurial one. Land release or administering the transfer of land use rights has become a means for local governments to channel investment into the city. Having been granted with the power to use land as resources to bring money to their cities, municipalities have effectively become "the actual manager of state property" (Haila, 1999: p. 585). In this process, the city itself has become an entrepreneurial entity.

In addition to the local state's role as the manager of state land assets, the rise of local states has been facilitated further by the proactive intervention of local states in the process of

economic transition as well as in the formation of the market. The state intervention in the market has been carried out to such an extent that the local state itself has become an active participant in the market rather than remaining only as the embodiment of the regulatory practices. Branches of administrative bodies have often transformed itself into state companies or joint ventures in order to participate in the markets such as real estate. Critics have been referring to these as the rise of 'local state corporatism,' 'local state entrepreneurialism,' and so on (Duckett, 1998; Oi, 1995; Shin, 2009).

Nevertheless, the rise of local states and their entrepreneurial turn are to be treated with caution especially in consideration of their relationship with the central state. As China experiences city-based accumulation, local states have also increased its territorial power. The key question is the extent to which this enhanced local autonomy reconciles with China's ongoing centralization of political power. From the perspective of intercity competition and economic decentralization, it may be possible to argue that local states seek ways in which they can be free of central state intervention. Local political elites may embark on strategies including strategic plan-making and the promotion of special economic zones to facilitate more inward foreign direct investment and the expansion of their accumulation capacities (Wu and Zhang, 2007). However, it is equally possible to envisage that the central state has strived to make sure their presence is felt in local policy making (Chen, 2009; Xu and Yeh, 2009). Alternatively, local states may aspire to their territorial ambition, both domestic and international, under the auspices of the central state (Shin, 2014b). It has been argued by various critics that the rise of key cities such as Shanghai as the world city has been supported by the central state (Wu, 2009). For instance, Xu et al. (2009) examine the process of land commodification and developmental politics, arguing that both local and central states engage in scalar politics to exert greater power in their own rights. In particular, they remind the attempts by the central state "to control the articulation of scales through which a more centrally consolidated power can be achieved" (p. 910). The territorial politics become ever more sensitive and complex as China sees the rise of various regional scales including city regions. Disposition of land as resources is often at the center of this politics, for the reasons as discussed above.

Remaking Chinese Urban Landscape

Spatial restructuring in Chinese cities has become the cause and outcome of China's rapid urbanization. It is a well-known fact that investment (that is, fixed capital formation) has been the most influential contributor to the macroeconomic development. Real estate investment in particular has been influential in the formation of gross domestic capital in cities at all levels. With the commodification of land and housing, major commercial housing projects have been carried out initially near suburban areas where land mobilization was relatively easier, and eventually in inner city areas in the form of urban redevelopment projects. The rise of household income as a result of China's economic development also provided a huge demand for improved housing conditions. The speculative environment in the real estate housing sector further prompted the notion of housing as an asset.

It is often discussed that work-unit compounds characterized the urban landscape of most Chinese cities. These work-unit compounds were the spatial representation of production and consumption spaces, and were the loci of microlevel politics that filtered the exercise of state power through the unique institutional forms of managers–workers relations (Bray, 2005; Walder, 1986). Spatially, work-unit compounds were effectively gated compounds that provided all daily necessities and family needs including nursery, schooling, medical care, and old age care. The quality of these provisions depended largely on the political strength and affluence of work-units. The administrative allocation of urban lands and the subordination of land use to production needs led to the homogenization of urban landscapes, minimizing the chances of spatial and social diversities.

Urbanization during the reform era brought about fundamental changes to the ways in which spatial production and consumption were organized. New spaces have emerged, catering for the needs of diverse urban interests including those of increasingly affluent urban residents, of local elites who often aspire to transforming their cities into 'world class cities,' and of migrants who struggle to settle down in cities. These new spaces may include art districts, central business districts (CBDs), gated commercial estates, heritage neighborhoods, monumental spectacles, and so on (Broudehoux, 2010; Pow, 2009; Ren and Sun, 2012; Shin, 2010, 2012). One of the major spatial manifestation that has captured the attention of urban critics is the presence of what is often referred to as 'urbanized villages,' 'villages-in-the-city,' or 'villages within a city.' These are former rural villages that have become urbanized in times of rapid expansion of neighboring urban areas. Having succumbed to the power of urbanization, these former rural villages come to exhibit a unique spatial expression of China's urbanization and informality particularly in southern China, where a huge influx of migrant population has been witnessed for many decades (Tang and Chung, 2002). Migrants' need of affordable rental housing is seen to have propelled the rise of such settlements, further fueled by the emergence of informal landlordism on the part of former villagers whose income generation opportunities were severely undermined due to the loss of agricultural income after farmland expropriation resulting from urban expansion. Critics often question the absence of urban sprawl in the manner as seen in other developing countries with rapid urbanization. Latin American cities have also seen the prevalence of informal settlements through land invasion, illegal subdivision, and informal extension. A close examination of the urbanized former rural villages and their emergence indicate a unique process of China's urbanization that involves a historic compromise between local states and village collectives, resulting in a less conflictual process of urban expansion.

The process of Chinese cities' remaking in recent decades has come with some huge costs especially in the form of local residents' displacement. Land assembly for the provision of various urban infrastructure and facilities or urban redevelopment projects targeting densely populated inner city districts have led to the displacement of hundreds of thousands of local citizens. For instance, the Geneva-based Centre on Housing

Rights and Eviction estimated on the basis of official records that about 1.5 million Beijing citizens would have been affected by various developmental projects between 2000 and 2008. This estimation does not take migrants into consideration and, therefore, the actual scale of displacement would far outweigh the official estimation (COHRE, 2007). In Shanghai, official data also suggest that about half a million households were affected by redevelopment between 2003 and 2010 (Shanghai Municipal Statistical Bureau, 2011). The scale of relocation and permanent displacement of local residents become particularly pronounced when cities embark on major developmental projects to address the aspiration to become 'world class cities,' a strategy that often accompanies the hosting of megaevents such as the 2008 Beijing Summer Olympic Games and the 2010 Shanghai World Expo (Shin, 2012).

Urbanization, Citizenship, and Rights Awareness

As the natural population growth in cities has been under control especially with the implementation of the One Child Policy since the early 1980s, China's urbanization is primarily driven by people's migration from rural counties to cities. This further raises questions about the usefulness of the household registration system that has been in place for decades since the late 1950s. Household registration was initially designed as a means to devise the ways in which place-based entitlements could be distributed. Rural residents were to have access to welfare entitlements provided by village collectives on the basis of their membership in the village collectives, while urban residents were to benefit from welfare provisions by their employers. Local governments intervened in the case of those few residents who failed to receive any kind of support from employers. Over time, the *hukou* system has become a tenacious measure to dissociate migrants with no permanent local *hukou* from accessing urban-based social services (Solinger, 1999), hence playing the role of invisible barrier to rural-to-urban migration. Migrants in cities were "still officially classified as temporary residents in the city and treated as noncitizens" (Zhang, 2002: pp. 317–318).

With the growing concern of inequalities and of more just distribution of economic benefits in urban areas, various localities are increasingly enacting urban and social policies in the manner that could be described as 'local citizenship'. That is, instead of making a strict distinction between urban and rural residents, the *hukou* system seems to transform itself into strengthening the division between local and nonlocal residents, emphasizing economic securities for local residents while minimizing benefits for nonlocal migrants (Smart and Lin, 2007). The shaping of local citizenship will see geographical unevenness. For those less affluent provinces and cities that aim to attract industries as well as compete for migrant workers, the *hukou*-related barriers are expected to be incrementally removed. More affluent cities may further raise the bar to selectively recruit qualified skilled migrant workers. The extent to which these uneven processes will reproduce dualism with regard to local and nonlocal citizens' access to urban services will require close examination in the future. This will also raise some important questions about the nature of citizenship in mainland China, especially with regard to the ways in which collective membership becomes the precondition for rights entitlement, and also with regard to the relationship between state citizenship, urban citizenship, and collective citizenship in rural areas.

Another important dimension is the issue of rights awareness and how the growing degree of rights claims communicate with the traditional notions of rights awareness in China. In particular, an increasing emphasis has been placed on building the middle class in China (Tomba, 2004; Zhang, 2010). This attracted attention not only from the scholars studying China's economic development and social progress but also from policy-makers and international consultancies. For domestic and global businesses, the expansion of middle class populations means greater buying power, creating opportunities to market high-end products including luxury goods. For policy-makers, their recent emphasis on boosting consumption is designed to supplement investment and sustain economic growth in times to come. For critics on China's societal progress, the middle class expansion raises the question of whether or not the expansion of China's middle class will bring about the rise of civil society and greater awareness and call for social, economic, and political rights. It is however unclear if the middle class populace will exert pressure on the state for more political reform. A recent study suggests that China's new middle class is keen to protect their individual rights but reluctant to exercise collective rights to challenge the state (Chen, 2013). Critics also point out that China's rights claims have been largely on economic subsistence (e.g., pay arrears), and there are signs that the middle class protests on various social and environmental issues are on the rise but rarely to the level of making claims against the state (Perry, 2008; Shin, 2013). Furthermore, the growth of the middle class populace in China is part of a dual process of middle class making and proletarianization of rural farmers in the urban contexts of exacerbating inequalities. For middle classes to be acting as the social agent of changes there is a need for them to find a common ground to form a broader cross-class alliance. This also requires a greater attention to what the position of working classes and farmers is going to be in a country that is arguably witnessing the "loss of a socialist state" (Lin, 2014: 43; see also Shin, 2014a).

Conclusion: Uneven Geography of China's Urbanization

This article has examined the contemporary trend of China's urbanization, the key drivers of this urbanization, and the major sociospatial outcomes and concerns. China's reintegration with the world economy during the post-1978 period has branded China as the 'factory of the world.' This was made possible by the presence of a rapidly growing number of migrant workers, central and local state policies to provide incentives and preferential treatments for inward investment, and China's geographical scale that enabled an economy of scale for domestic production and consumption. From the perspective of local states, the urbanization has increasingly become synonymous with the process of local state building.

As local governments are delegated with the power to administer the transaction of urban land use rights on the basis of state-ownership of urban lands, territorial politics have become prevalent especially with regard to gaining control on land resources, which are nowadays prominent sources of financing investment in fixed assets.

The article has also discussed some of the major sociospatial outcomes of China's urbanization, focusing on the remaking of Chinese cities that accompanied the rise of CBDs to bring the urban landscape to meet the urban aspiration to become global in appearance. While Chinese cities used to share the key characteristics of 'socialist cities' during the era of planned economy, they have trodden the path of diversity and heterogeneity, seeing the emergence of various cityscapes that range from commercial gated communities and heritage neighborhoods to art districts, and the CBDs. Together with heavy investment in urban infrastructure and facilities, these developmental projects nevertheless produce heavy costs for on-site residents. Official aggregate estimations often report millions of local citizens being affected by these projects, and these numbers are largely underestimated as migrant tenants are largely excluded from the counting. Major cities often produce explicit policies to depopulate city centers, and transform the area to meet the demands of domestic and foreign professionals and investors, thus paving the way for the class remake of urban space.

As China's 'urban age' is expected to intensify under the Party State, the remaining question is its long-term stability of current development models. Discussions on this topic propel China observers to think of the value of China studies and its contribution to the general scholarship. For instance, while China's development thus far has focused on major sites of accumulation along the eastern coastal region, more attention is now being paid to its hinterlands, that is, central and western regions. In order to further boost both investment and consumption, cities in central and western regions may hold the key to the future of China's sustainable economic development to similar rates as experienced during the post-1978 reform period. This requires the decentering of urban China studies away from major cities such as Beijing and Shanghai. It is no unknown secret that urban China studies have been concentrated on a selected few number of cities (or on a so-called 'first-tier' cities). China's urbanism is expanding to influence lower-tier cities in China, and the new leadership's drive for further urbanization will require the growth of smaller towns and counties where there are more rooms for expansion. It will be necessary for China scholars to closely examine the conditions of urban accumulation and city-remaking therein. The other major issue will be the extent to which political stability at all geographical scales (i.e., urban, regional, and national) will be maintained. The CCP has been reinventing itself to adopt to the changing social, economic, and political contexts (the best known example being the admittance of entrepreneurs as Party members since 2003), but it has also proven its strict, brutal approach when social protests have made attempts to make cross-class or cross-regional alliances. The rise of middle classes and their increasing demands for better living conditions and the security of their household assets have the potential to be turned against the state itself. The aggravating inequalities and the continued pursuit of proletarianization of rural surplus labor will exert pressure on the state, while growing gaps between the new middle class and the new urban poor also become a major source of concern. To this extent, the long-term prospect of China's urbanization hinges upon the way in which political stability can be maintained by the state, especially in times of cyclical economic difficulties generated domestically as well as globally. This also makes it important for China observers to closely follow the rise of discontents and rights claims, and scrutinize the ways in which Chinese Party State responds to these.

Utilitarian Social Thought, History of

James E Crimmins, The University of Western Ontario, London, ON, Canada

Abstract

The beginnings of utilitarian social theory can be traced to Greek philosophy. In the late seventeenth and early eighteenth centuries, it began to take on its classical form. Jeremy Bentham is usually identified as the fountainhead of the doctrine, but the contributions of Hutcheson, Hume, Beccaria, Helvétius, Godwin, and the 'religious utilitarians' should also be noted. After Bentham, the theory received its most celebrated treatment by John Stuart Mill. The article describes the essential elements of utilitarian theory, delineates the dissemination and development of utilitarian ideas, explores problems of theory and interpretation, and provides a survey of later developments.

Standard utilitarian theory is underwritten by the following moral claims: the rightness/wrongness of an action is determined by the goodness/badness of its consequences; the only thing that is good in itself is pleasure and the only thing bad in itself is pain; and happiness/misery is constituted of the aggregation of pleasures and pains. Implicit in this ethical hedonism is the premise that the motives to action are rooted in self-interest. Based on these elements, the doctrine is then expressed in the form of the greatest happiness principle – that is, the rightness of an action is determined by its contribution to the happiness of everyone affected by it. In *A Fragment on Government* (1776) the legal philosopher Jeremy Bentham (1748–1832) declared it "a fundamental axiom" that "it is the greatest happiness of the greatest number that is the measure of right and wrong," and that "the obligation to minister to general happiness, was an obligation paramount to and inclusive of every other" (Bentham, 1977: pp. 393, 440–441). In 1781, in recording a dream in which he imagined himself as the founder of a "sect", Bentham coined the name "utilitarian" for this theory (Crimmins, 1990: p. 314).

Origins

Although Bentham is usually cited as the founder of utilitarianism, the antecedents of utilitarian principles have a far older vintage in the philosophy of Plato, Aristotle, and Epicurus, and in early Christian thought (Scarre, 1996: Chapter 2). Other significant dimensions of the theory can be traced to the seventeenth century writings of Thomas Hobbes, John Locke, and Richard Cumberland. However, it was the 'moral sense' philosopher Francis Hutcheson (1694–1746) who first cast the objective of morality in explicitly utilitarian terms when he wrote, in *An Inquiry into the Original of our Ideas of Beauty and Virtue* (1729), "*that Action is* best, which accomplishes the *greatest Happiness* for the *greatest Numbers*; and that, worst, which in *like manner*, occasions *Misery*" (Hutcheson, 2004: p. 125). In addition, Hutcheson speculated about the appropriateness of 'applying mathematical Calculation to moral Subjects', including the possibility of assessing happiness in terms of 'addition' and 'diminution', and hazarded the view that what matters in calculating the virtue of an action is the degree of happiness and "the Number of Persons to whom the Happiness shall extend" (Hutcheson, 2004: pp.123, 125, 128). By indicating that quantities and the extent of happiness matter in making moral claims Hutcheson set the agenda for later utilitarian moralists, though he himself continued to believe that the disinterested motive of benevolence was the foundation of virtue and later expunged all traces of the discussion of mathematical calculation in moral matters from subsequent editions of the *Inquiry*.

Like Hutcheson, William Godwin (1756–1836), in *An Enquiry Concerning Political Justice* (1793), also stipulated that virtue was located in 'universal benevolence', in seeking the pleasures of others (Godwin, 1793: vol. 1, pp. 87, 106). Nor, again like Hutcheson, could he be considered an outright consequentialist, since he believed that a man's 'disposition' was a surer guide to virtue than his actions (Godwin, 1793: p. 122). On the other hand, in a similar vein to Bentham, Godwin depicted society as a simple aggregate of individuals and subscribed to the view that justice, properly understood, was 'coincident with utility' (Godwin, 1793: pp. 90, 121). The gulf between Godwin and Bentham widened considerably, however, in their reflections on the purpose of law. For Godwin, reputedly the first philosophical anarchist, law was only a temporary aid to virtue. In the belief that men are not perfect but are perfectible (Godwin, 1793: p. 118), Godwin argued that moral instruction was the principal way to bridge the conflict between egoism and benevolence. Once individuals properly understood their duty to act in the public interest, then the sanctions of law would become redundant. The optimism embedded in this idea led Godwin to envisage a time when societies might be able to function entirely on the principle of cooperation to produce the greatest happiness without the need for government.

It was in the moral philosophy of the eighteenth-century religious advocates of the utility principle that utilitarian theory began to assume its classic form. Proponents of religious utilitarianism included John Gay (1699–1745), John Brown (1715–66), Edmund Law (1703–87), Abraham Tucker (1705–74), and William Paley (1743–1805). The ethical hedonism developed by these moralists was premised on the existence of a God who would punish and reward in the afterlife according to the degree to which individuals acted to enhance general happiness in the present life; in short, personal happiness – encompassing the prospect of eternal happiness in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03143-3

the life to come – is achieved by pursuing social happiness in the here and now (Crimmins, 1998). Gay's major contribution to the utilitarian tradition is the theory of 'associationism', which explained actions based on habit and was further developed and given common currency by David Hartley (1705–57). Hartley's theory of association is a constituent assumption in the thought of nearly all the later utilitarians and in particular was a major influence on James Mill.

Among the religious exponents of utility, only Paley offered a comprehensive and systematic social philosophy founded upon the utility principle, encompassing morals, government, law, and political economy, in his popular *Principles of Morals and Political Philosophy* (1785). But Paley's politics, with certain liberal exceptions (religious toleration and the abolition of slavery), was essentially conservative, and his moral theory tended to encourage complacency toward the causes of misery in the present life (Crimmins, 2013a).

Bentham's secular version of the theory was derived from a more progressive strain of enlightenment thought: empirical, analytical, and antagonistic toward religious beliefs and other moral mythologies. Unaware of Hutcheson's formulation of the utility principle, Bentham attributed it to the Italian law reformer Cesare Beccaria (1738–94) and sometimes to the dissenter and natural philosopher Joseph Priestley (1733–1804). Other progenitors to whom he traced his intellectual inheritance included David Hume (1711–76) and Claude Helvétius (1715–71) (Rosen, 2003: Chapters 3 and 5). In Hume's secular moral philosophy, the source of the rules of justice were located in general utility, but he explained the psychology of moral conduct in terms of a theory of 'moral sentiments' rather than motives supplied by pleasures and pains. Bentham's acknowledgment of the importance of Hume was tempered by his general irritation with the subjectivism of the Scottish 'moral sense' school, and by Hume's failure to apply the utility principle as a critical tool of analysis and guide to social improvement (Crimmins, 2011a: Chapter 3). In *De l'esprit* (1758), Helvétius provided a systematic if rudimentary explanation of human motivation in terms of utility perceptions and expectations and some useful suggestions for the application of this knowledge to law and other social questions. But his philosophy lacked the systematic arrangement, conceptual clarity and rigor necessary for a 'science' of morals and legislation. This is what Bentham set out to supply.

Bentham's Science of Morals and Legislation

In *An Introduction to the Principles of Morals and Legislation* (1789), Bentham delineated the component parts of his 'science' of morals and legislation founded upon the utility principle. The general purpose of the science was "to rear the fabric of felicity by the hands of reason and of law" (Bentham, 1970: p. 11). The *Introduction* was then considered by Bentham to be the foundational text of his legal philosophy and his plans for future works were intended to elucidate the practical application of the utility principle in the areas of civil and penal law, judicial procedure, legislative reward, constitutional law, legislative procedure, international law, finance, political economy, and 'universal jurisprudence' (Bentham, 1970: pp. 5–6).

The Principle of Utility

At the base of Bentham's theory was the assumption of "the governance of two sovereign masters, *pain* and *pleasure*. It is for them alone to point out what we ought to do, as well as to determine what we shall do" (Bentham, 1970: p. 11). As a first principle used to establish everything else, the utility principle was not itself subject to proof, but Bentham claimed, there was sufficient testimony to the fact that it had always been generally accepted as the standard of right and wrong (Bentham, 1970: p. 13). This foundational principle referred to a feeling or sentiment that served to approve the utility of an action. As Bentham explained, "The principle here in question may be taken from an act of the mind; a sentiment; a sentiment of approbation; a sentiment which, when applied to an action, approves of its utility, as that quality of it by which the measure of approbation or disapprobation bestowed upon it ought to be governed" (Bentham, 1970: p. 12). Utility also meant public utility, and the utility of the individual was a part of the public utility in which the individual shared. Thus a person approved of an act or law to the degree to which the happiness of all the individuals in 'the community in question' were advanced. For Bentham, the relationship between happiness and pleasure and pain was straightforward and did not require elaboration: pleasure contributes to happiness, while pain detracts from it. In these terms the public interest is constituted of the aggregate of individual interests, construed in terms of the balance of pleasures and pains experienced by each person.

Bentham's intention was not that the agent should only consider his own personal interests when contemplating action, nor that we should *always* bear in mind the happiness of the whole of humanity. Rather, when a person considers the utility of an action he should take into account the impact of the action on the interests or well being of those he knew would be affected by it: where the action concerns only the agent, then that is the only interest to be considered; when the action impacts upon others, then their interests must be counted too; and when lawmakers enact a new law or policy it is the impact on the happiness of the people at large they must bear in mind, up to and including the inhabitants of an entire society, and quite possibly the inhabitants of other societies. At his most universal Bentham, who was responsible for introducing the new word 'international' into both the French and English languages, held that the object of international law is "the greatest happiness of all nations taken together" (Bentham, 1838–43: vol. 2, p. 538).

Motives and Consequences

For Bentham all motives have their source in the anticipation or expectation of pleasure or pain. He delineated four *sanctions* or sources of pain and pleasure, which he may have learned from either Locke or Gay: physical, political, moral, and religious. These sanctions are available to the moralist and to the legislator in guiding and determining an individual's moral conduct, and explain how an essentially self-interested individual can be directed to perform actions, which enhance general happiness. In Bentham's theory of motives, the dictates of utility were neither more nor less than the dictates of the most extensive and enlightened benevolence. Other motives

were categorized either as 'semisocial' motives (such as love of reputation, desire of amity, and those rooted in religion), which may or may not coincide with the principle of utility, and purely 'self-regarding' motives (such as physical desire, pecuniary interest, love of power, and self-preservation), which were the least likely to coincide with utility. All motives, however, including the most extensive benevolence, are rooted in self-interest in one form or another; in these terms, the notion of a *dis*interested motive is implausible.

While the consequences of an act are partly dependent on the motives which give birth to the act (and partly on the empirical circumstances in which the act is performed), in Bentham's theory the utility of an act is not dependent on its originating motive(s). The relative utility of an act is determined solely by its consequences: the advantages and/or disadvantages that result. When deciding whether to act or which act to perform the individual must calculate as best as he or she can the pleasures and pains which may reasonably be expected to accrue to the persons (including him- or herself) affected by the acts under consideration. Bentham's famous *hedonic* or *felicific calculus* (he did not use these terms) by which the value of pleasure and pain may be reckoned was constituted of the following elements: intensity, duration, certainty or uncertainty, propinquity or remoteness, fecundity, purity, and extent. A similar calculation should guide the legislator in formulating policy and law, though Bentham recognized that precision in such matters could only be impressionistic – the closer the calculation came to the 'ideal' the greater the prospect of devising effective measures. Moreover, Bentham recognized that it was not normally feasible nor rational for an individual to engage in repeated calculations prior to acting in everyday life, hence he spoke of habit (based on association) as the general source of action and an understanding of the general tendencies of actions to enhance or diminish happiness as sufficient to guide us in most situations.

Punishment and the Panopticon

The consequences of acts were central to Bentham's theory of punishment, in part derived from Beccaria's path-breaking treatment of the subject in *On Crimes and Punishments* (1764). The utilitarian objective of criminal law is general deterrence and this is served by ensuring that punishments are in proportion to the mischiefs produced by crime. To this end Bentham developed a series of rules to guide the lawmaker in the construction of a utilitarian penal code, including the elements involved in the calculation of the mischief caused by an offense and the form and degree of punishment necessary to effect deterrence (Crimmins, 2011b). Following Beccaria, though on more clear-cut utilitarian grounds, Bentham opposed the death penalty, arguing that deterrence in capital crimes is best served by the example of offenders serving life in prison with hard labor.

Bentham's controversial panopticon, best known as the design for a circular prison in which prisoners lived under the apprehension of constant observation by officials positioned in a central watchtower, has occasioned a good deal of attention over the years since its inception in the late 1780s. Michel Foucault famously took the perspective that *panopticism* defined a 'new physics of power', an experimental 'laboratory of power' in which behavior could be modified, and viewed the panopticon as a symbol of the repressive, disciplinary society, the modern 'society of surveillance' (Foucault, 1977: p. 208). This view of the panopticon has opened some interesting lines of discourse on the encroaching methods of social control in contemporary liberal societies. As a critique of Bentham's proposals, however, it is less impressive.

In *Panopticon; Or the Inspection House* (1791) Bentham gave practical expression to the utilitarian theory of punishment by stipulating a range of subordinate principles to which his circular prison should conform: economy, since the prison should be a private self-sustaining operation based on the productive labor of the inmates and not require financial assistance from the public; severity, because it was necessary for the offender to suffer to serve the ends of general deterrence and personal reformation; and humanity, which prescribed that prisoners should be deprived only of liberty not of health or life. Upon their release, reformed convicts should be able and willing to live on the rewards of their own labor. To these guiding principles Bentham added several devices to produce transparency and accountability, chief among them opening up the operations of the prison and its officials to public scrutiny (Semple, 1993).

Bentham also speculated about the application of the panopticon idea to other institutional arrangements in which a high degree of supervision of the 'inmates' would produce beneficial results, including hospitals, asylums, poor houses, factories, and schools. He developed a myriad of improvements to accompany such buildings, and in particular devoted an extraordinary amount of time to poor law reform (Bentham, 2001, 2010), but did not live to see the construction of a panopticon of any sort. In later life, when he was primarily occupied with developing a complete code of laws for 'all nations professing liberal opinions', he found time to advocate reform of the laws governing anatomical research and willed his own body for public dissection following his death in 1832 (Crimmins, 2002). Two of the greatest social campaigners of the first half of the nineteenth century, the medical and health reformer Thomas Southwood Smith (1788–1861) and the poor law and factory reformer Edwin Chadwick (1800–90), worked closely with Bentham in this period and developed their ideas under his influence.

John Austin

Although sometimes described as an act utilitarian, it is generally acknowledged that for Bentham properly constituted *rules* based on calculations of general utility, ought to be the guides for human action (Baumgardt, 1966). John Austin (1790–1859), a disciple of Bentham's jurisprudence, is usually cited as the first explicit rule utilitarian. However, in *The Province of Jurisprudence Determined* (1832), he made it clear that he learned the significance of rules from Paley, from whom he also borrowed the theological elements of his theory. Austin became acquainted with utilitarianism during his undergraduate years at Cambridge. In 1821 he was hired to tutor J.S. Mill in Roman law, began attending meetings of the Utilitarian Society established by the younger Mill in 1823, and in 1826 was appointed to the Chair of Jurisprudence at the newly founded University of London. Austin's legal philosophy had a major impact on

English and American jurisprudence, described by one commentator as "a canonical statement of modern legal positivism and analytical jurisprudence" (Lieberman, 2013).

James Mill

James Mill (1773–1836) has often been credited with influencing Bentham's conversion to democratic principles in 1808–09; however, Bentham had already developed utilitarian arguments for democratic reform in manuscripts written around the time of the French Revolution. What Mill certainly brought to the political cause of utilitarianism was clarity of expression, which he employed to telling effect in his *Essay on Government* (1819). Based on the premise that government has the purpose of producing the greatest happiness of the greatest number, in this essay Mill made a succinct case for substantive parliamentary reform (universal manhood suffrage, secret ballot, and annual parliaments). Nevertheless, Mill was taken to task by the Irish Benthamite socialist William Thompson for excluding women from the proposed reform of the franchise (*Appeal of One Half of the Human Race Women against the Pretensions of the other Half Men*, 1825). More famously, the Whig T.B. Macaulay mounted a biting criticism of Mill's essay in the *Edinburgh Review* in 1829, largely for its narrow view of human nature and a priori science of politics. Both Bentham and the younger Mill sided with Thompson on votes for women, though for tactical reasons Bentham remained silent on the question when presenting his mature democratic theory in *Plan of Parliamentary Reform* (1817) and other constitutional writings from the 1820s. Nor were Bentham and the younger Mill impressed by James Mill's recommendation that the vote be based on a modest property qualification and limited to men over the age of 40; they opted for universal suffrage at the age of 21, subject only to a literacy test. Mill also considered the advantages of proportional representation and plural voting in *Thoughts on Parliamentary Reform* (1859) and *Considerations on Representative Government* (1861).

Dissemination of Utilitarian Ideas

Bentham's writings – with the notable exceptions of *A Fragment on Government* and *Defence of Usury* (1787) – were often disparaged for their tortuous style, marked by the irksome use of parentheses and a distracting tendency to convey ideas in newly minted terminology. It is doubtful that he would have achieved an extensive reputation as a moralist and legal philosopher had it not been for the Genevan lawyer Étienne Dumont (1759–1829), who assumed the role of Bentham's translator and editor, and fashioned an international audience for his work. In 1802 Dumont published *Traités de législation civile et pénale* (3 vols., 1802), the main parts of which were the treatises on civil and penal law, and followed this with several other publications based on Bentham's writings: *Théorie des peines et des récompenses* (1811), *Tactiques des assemblée législatives, suivi d'un traité des sophismes politiques* (1816), *Traité des preuves judiciare* (1823), and *De l'organisation judiciaire et de la codification* (1828). None of these texts was a straightforward translation of Bentham, but are rather styled redactions or recensions, either edited from Bentham's original papers or combining manuscript material with extracts from published works. In this form utilitarian ideas reached many more readers than Bentham ever could have hoped (Crimmins, 2014).

After its initial circulation in France, the *Traités* was translated into Russian, Spanish, German, Hungarian, Polish, and Portuguese. Reportedly, 50 000 copies of Dumont's various recensions were sold in Europe in the early decades of the century and 40 000 in Spanish translation in Latin America alone, where Bentham's ideas were adopted in the nascent law schools. The impact of utilitarian ideas on legal education in the United States began with David Hoffman (1784–1854) and his celebrated *A Course of Legal Study* (1817, revised and expanded 1836), later complemented by *Legal Outlines* (1829). Soon after, the 'American Utilitarian' Richard Hildreth (1807–65) translated the main parts of Dumont's *Traités* as *Theory of Legislation* (1840) – a work destined to remain at the center of utilitarian studies in the English-speaking world through to the middle of the twentieth century – and followed that with his own utilitarian *Theory of Morals* (1844).

The reaction to the spread of utilitarianism in the United States was mixed: praise for Bentham's legal philosophy, particularly the theory of civil law, was offset by objections to its underlying moral assumptions and disdain for religion. Among the notable American intellectuals inspired by Bentham in this period were Thomas Cooper (1759–1839), a prolific author and controversialist whose writings included political economy, law, science, and philosophy; Edward Livingston (1764–1836), the famous author of codes of law for Louisiana who acknowledged Bentham as the world's leader in this domain; and John O'Sullivan (1813–95), the quixotic editor of the *United States Magazine and Democratic Review* who wrote sympathetic reviews of Bentham, Livingston, and Hildreth, and followed them in advocating utilitarian law reform, particularly the abolition of capital punishment. Bentham's influence continued throughout the century in America, where the *Traités* paved the way for the reception of other editions and versions of his writings, which in turn led to sympathetic responses to the more amenable forms of utilitarian moral and legal theory offered by Austin, Mill, and Henry Sidgwick (Crimmins and Spencer, 2005).

John Stuart Mill

In his *Autobiography* (1873) Mill relates that when he first encountered Bentham's ideas in Dumont's edition of the *Traités* "I now had opinions, a creed, a doctrine, a philosophy; in one among the best senses of the word, a religion; the inculcation and diffusion of which could be made the principal outward purpose of a life" (Mill, 1963–91: vol. 1, pp. 67–8). Later, partly in response to the challenge of Macaulay's criticism of his father and partly the result of his own reflections on his intellectual inheritance, he developed a revised version of utilitarian theory. This revisionism was first announced to the world in the essay 'Bentham' (1838) and received definitive expression in *Utilitarianism* (1861). In the latter, Mill sought to defend the basic hedonism of utilitarian theory while offering refinements designed as responses to critics of the doctrine. The most problematic of these is the

distinction between the *qualitative* differences of types of pleasures, a view first enunciated in rudimentary form in Paley's *Principles*.

While adhering to the basic Benthamic analysis of motives, Mill introduced the concept of higher pleasures, by which he meant the pleasures of the intellect, which he claimed were intrinsically more desirable than other pleasures. However, this qualitative distinction undermined the aggregative dimension of the theory and introduced questions concerning the appropriate judge of which pleasures were preferable. Mill only raised further questions about the integrity of the theory by arguing that the constituent elements of an individual's happiness might encompass objectives, such as the pursuit of truth, beauty, and virtue, without consideration for the utility they may bring. This was a view later adopted by G.E. Moore (1873–1958) in the *Principia Ethica* (1903). Rejecting the hedonism of Bentham and Mill, Moore set forth a 'consequentialist' theory now known as *ideal* utilitarianism, in which the 'good' to be attained is more expansive than the summation of pleasures, and contains within itself certain objective features of the universe, preeminently the beauty of its constituent parts (Scarre, 1996: p. 114).

In other respects, Mill's utilitarianism remained within the Benthamic framework. To the criticism that utilitarianism sacrificed principles for expediency, he replied that it was expedient to observe the *rules* associated with general utility and implied that only saints could be thoroughgoing utilitarians, able to calculate continually the consequences of their actions. Like Bentham too, Mill gave priority to security in explaining the objectives of a system of justice. Finally, the supposed conflict between utilitarianism and Mill's commitment to individualism and individual liberty in the essay *On Liberty* (1859) is resolved when liberty is defended, not for its own sake but on the utilitarian grounds of the benefits, which accrue to the individual and to the society of which the individual is a member.

Individualism and Collectivism

Utilitarianism has enjoyed a sustained if ambiguous presence within the liberal tradition. Bentham's 'liberalism' is largely based on his writings on civil law and political economy, where he introduced subordinate principles to guide the legislator in giving effect to the utility principle: security, subsistence, abundance, and equality. The stress on the *security* of the individual and *security of expectations* gave a priority to individual liberty when crafting law and tended to introduce a conservative element into the legislator's reform agenda, while the egalitarian principle held out the prospect of redistributive policies. Which of the subordinate principles was most in accord with the dictates of utility at any one point, and therefore should be acted upon by the legislator, depended on the particular context and particular issue. To the 'security-providing' principle Bentham later added the 'disappointment-preventing' principle. Security required that legitimate expectations associated with property and place ought not to be disappointed, but where this is not possible (as in a time of crisis, such as famine or military defense) or when manifestly beneficial social improvements may be introduced without causing general concerns about the protection of security, then disappointed expectations (loss of public office as a result of necessary administrative reform or loss of land under a compulsory purchase order in the public interest, for example) must be compensated in the legislative process.

Bentham shared Adam Smith's view that each person is the best judge of their own interests. The route to a nation's prosperity is by individuals pursuing their interests in ways of their own choosing, and government intervention should be limited accordingly. However, Bentham also developed the theory of diminishing marginal utility, which dictated that one could have too much of a good thing; beyond a certain threshold the utility value of pleasures to an individual would begin to diminish. This furnished the legislator with an additional conceptual tool when considering the uneven distribution of social happiness and suggested policies to redistribute wealth and resources. The collectivist conclusions Bentham drew from this were modest in scope, but later economists, like W.S. Jevons (1835–82), developed the theory in the direction of modern welfare economics. F.Y. Edgeworth (1845–1926) and the Fabian socialists Sidney (1859–1947) and Beatrice Webb (1858–1943) were also important in applying utilitarian ideas to maximize and better distribute 'total utility' (see the relevant articles in Crimmins, 2013b).

Commentators who emphasize the importance of the subordinate principles that inform Bentham's theory of civil law and political economy tend to view him as an *individualist* or *liberal* utilitarian, who intended that laws should be modeled to facilitate individuals in the pursuit of happiness in ways they, rather than the legislator, thought appropriate (Kelly, 1990). This interpretation contrasts with the traditional view of Bentham as an aggregative legislative utilitarian. Mill is also interpreted as a *liberal* utilitarian, whose theory of justice stressed the utility value of *security* of the person and property (Riley, 1998). This placed definable limits on the functions of law and implied a gradualist approach to achieving optimal utilitarian outcomes through social and political reforms. Nevertheless, in a society of literate people neither Bentham nor Mill saw any barriers to the introduction of democratic institutions, including the extension of the suffrage to women on equal terms with men. Moreover, in later life Mill inclined toward collectivist solutions to social problems (Riley, 1996).

In *Man versus the State* (1884) and other writings, Herbert Spencer (1820–1903) employed the utility principle to enhance the liberty of the individual, defend the existing social order, and attack the drift toward socialism and 'slavery.' James Fitzjames Stephen (1829–94), Henry Sidgwick (1838–1900), and A.V. Dicey (1835–1922) all advocated versions of utilitarian individualism, although Sidgwick occasionally gave voice to 'socialist' sentiments in developing his *intuitional* utilitarian theory in *The Methods of Ethics* (1874). Reform-minded liberals such as J.A. Hobson (1859–1940) and L.T. Hobhouse (1864–1929) found in the protean nature of utilitarianism a justification for distinctly nonindividualist policies. Thus Hobhouse in *Liberalism* (1911) incorporated utilitarianism into a new liberal discourse that, in addition to laissez-faire economics (and notwithstanding Herbert Samuel's quasi-Benthamic motto 'the greatest liberty of the greatest number') also bridged elements of socialism, social

Darwinianism, and the idealism of T.H. Green (1836–82), and out of which emerged the beginnings of Britain's welfare state.

Criticisms

In the nineteenth century, utilitarianism was assailed from all sides: by sundry religionists, intuitionists like William Whewell (1794–1866), and idealists like Green, F.H. Bradley (1846–1924), Bernard Bosanquet (1848–1923), and D.G. Ritchie (1853–1903). If Marx considered utilitarianism an ephemeral bourgeois ideology, the latter critics combined to attack its atomism, crude materialism, narrowly construed theory of motivation, and lack of appreciation of the spiritual dimension of the human condition (Mill notwithstanding).

One of the most effective modern criticisms of utilitarianism is found in John Rawls' *A Theory of Justice* (1971). Rawls argued that in counting *only* interests and aggregating *across* persons to arrive at the appropriate action or policy the utilitarian fails to 'take seriously' the distinction between persons. In reply it could be argued that at the level of private ethics utilitarian calculations implicitly acknowledge that different and distinct persons are involved in most situations about which individuals have to make moral judgments. This means that a consistent utilitarian will treat the interests of different people affected by his or her actions as of equal importance. However, the problem with this reasoning is that it risks making utilitarianism primarily a theory of equal consideration and effectively relegates the aim of maximizing utility to the status of a byproduct, not the ultimate ground of the theory. This remains an unresolved tension in utilitarian theory. Critics of the theory, for example, frequently note the unpalatable sacrifices entailed by simple calculations of optimal utility to social problems; in an indiscriminate calculation where only total quantity of pleasures count, minorities are especially vulnerable to risk. Although Bentham was aware of the problems associated with the potential exclusion of minority interests under the phrase 'the greatest happiness of the greatest number', the literature on utilitarianism abounds with discussions of the potentially negative consequences of employing unqualified aggregative calculations of social utility. This debate is represented in the exchange between the modern act utilitarian J.J.C. Smart and his critic Bernard Williams in *Utilitarianism: For and Against* (1973). Many other dimensions of the history and theory of utilitarianism and the numerous debates associated with its ideas and their practical application are explored in *The Bloomsbury Encyclopedia of Utilitarianism* (2013).

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Valency and Argument Structure in Syntax

Jae Jung Song, University of Otago, Dunedin, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The purpose of this article is to explain the valency and argument structure of the predicate. The article begins with definitions of valency and argument structure. This then leads to illustration of a number of ways in which arguments are removed from, or added to, the argument structure, whereby changes in the valency of the basic predicate may be brought about. The article demonstrates that the argument structure can also be altered or rearranged without involving a change of valency. Also illustrated is how languages may keep the valency of the derived predicate from exceeding that of the basic predicate. The article addresses the question of whether or not identical coding of nominals – especially in the context of valency increasing – entails doubling of grammatical relations. Finally, a brief discussion of how valency-changing operations are handled or represented in current grammatical theories is provided.

The purpose of this article is to describe the valency and argument structure of the verb or predicate. The notion of argument is known to have been adapted from mathematics. In mathematics, a function may take one or more arguments, which will be used to determine the value of that function. In linguistics, argument is used as a technical term for syntactic elements that combine obligatorily with the verb (or the predicate as the verb is usually referred to in relation to arguments). For instance, the English verb *die* must take at least one syntactic element, e.g., *the mayor*, to form sentences, e.g., *The mayor died*. This syntactic element is taken to be the (sole) argument of the predicate *die*. The verb *kill*, on the other hand, requires two arguments to form sentences, one representing the killer (*the man*) and the other the person killed (*the mayor*), as in *The man killed the mayor*. The number of arguments that are required by a predicate is then specified in the argument structure of that predicate. Additional syntactic elements, e.g., *in the office* or *in 2011*, can also potentially combine with the predicate *die*, e.g., *The mayor died in the office*, *The mayor died in 2011*, or *The mayor died in the office in 2011*. But these are regarded only as optional, because their absence has no bearing upon the grammaticality of the 'minimal' sentence, *The mayor died*. Such optional syntactic elements are referred to as adjuncts. The distinction between arguments and adjuncts, albeit not always easy to make, is a useful one (see Comrie, 1993 for a discussion on how arguments and adjuncts should be distinguished).

The argument structure also contains information concerning the relation between the predicate and its argument(s). For instance, in the sentence *The man killed the mayor*, the predicate *kill* and its arguments *the man* and *the mayor* have logical (or grammatical) relationships between them with the effect that *the man* is the actor (or the subject) that carried out the killing, and *the mayor* is the undergoer (or the direct object) that was affected by the actor's killing (see Grammatical Relations; also Bickel, 2011 for an overview of grammatical relations). Adjuncts, e.g., *in the office* in *The mayor died in the office*, also bear logical (or grammatical) relationships, e.g., location (or oblique), with the predicate. Information on adjuncts, however, is not included in the argument structure of the predicate itself.

The term valency (or valence in the USA) is said to have been borrowed from chemistry into syntax. In chemistry, the valency of a chemical element is defined as the capacity of that element for combining with a fixed number of atoms of another element, for instance, two hydrogen atoms combining with an atom of oxygen in the case of water (i.e., H_2O). The notion of valency, when applied to verbs, refers to the number of arguments that are required for a given verb to form sentences. For example, the verb *die* is regarded as having a valency structure of a single argument. Thus, verbs such as *die* are characterized as one-place (or monovalent) verbs. The verb *kill* is a two-place (or divalent) verb, because it requires two arguments. The verb *give* is a three-place (or trivalent) verb, because it requires three arguments.

The rest of the article is concerned principally with illustrating how argument structure can be altered or manipulated with or without a concomitant change of valency. How languages may keep the valency of the derived verb from exceeding that of the basic verb by manipulating argument structure will also be described (see Morphology in Linguistics for derivation; also Comrie, 1985). Finally, how

valency-changing operations are handled in current grammatical theories will be discussed briefly.

Change of Argument Structure with Change of Valency

There are two main mechanisms through which the argument structure of the predicate can be altered, together with a change of valency: argument reduction and argument addition. In argument reduction, one of the arguments of the basic predicate may be demoted to adjunct status. In argument addition, on the other hand, adjuncts may be promoted to argument status, or new arguments may be introduced into the argument structure. There are five important grammatical devices utilized in argument reduction or argument addition: passivization, antipassivization, noun incorporation, advancement, and causativization. The first three belong to argument reduction, whereas the last two fall under argument addition (but cf the section Change of Argument Structure without Change of Valency for examples of noun incorporation and causativization consisting of both argument reduction and addition).

Passivization

In the passive clause, one of the arguments of the basic two-place predicate (i.e., the actor) is demoted to an adjunct with the other argument (i.e., the undergoer) retaining its argument status (but being promoted to the subject of the passive clause). This operation is referred to as passivization (e.g., Abraham and Leisiö, 2006; Siewierska, 1984, 2005). The number of arguments of the basic predicate is thus reduced from two (i.e., the actor and undergoer) to one (i.e., the undergoer) in the corresponding passive clause. This is substantiated by the fact that it is possible to omit the newly created adjunct. This change of valency (or valency decreasing) is signaled on the verb either by a verbal affix or by a periphrastic element in the verb phrase. Korean provides an example of the passive:

1. Korean

cuin-i	totuk-lɨl	cap-əss-ta
owner-NOM	thief-ACC	catch-PST-IND

'The owner caught the thief.'

2. Korean

totuk-i	(cuin-eke)	cap-hi-əss-ta
thief-NOM	(owner-by)	catch-PASS-PST-IND

'The thief was caught (by the owner).'

(Abbreviations used to gloss the data: ABS = Absolutive; ACC = Accusative; APASS = Antipassive; APPL = Applicative; ASP = Aspect; AUX = Auxiliary; CS = Causative Suffix; DAT = Dative; DEM = Demonstrative; DET = Determiner; DO = Direct Object; ERG = Ergative; F = Feminine; FUT = Future; INCMP = Incompletive; IND = Indicative; INTR = Intransitive; IO = Indirect Object; IPFV = Imperfective; LOC = Locative; M = Masculine; NFUT = Non-Future; NOM = Nominative; O = Object; OBL = Oblique; PASS = Passive; PERF = Perfective; PL = Plural; PRS = Present; PST = Past; S = Subject; SG = Singular; TR = Transitive; Q = Question.)

In some languages (e.g., Finnish, Nanai, Ulcha, and Ute), passivization involves only demotion of the actor of the basic predicate, with the undergoer remaining unaltered in its grammatical status (i.e., direct object). This is illustrated in

3. Ulcha

ti	dūse-we	hōn-da	ta-wuri
DEM	tiger-ACC	how-Q	do-PASS

'What's to be done about that tiger?'

Antipassivization

Antipassivization is often regarded as the counterpart of passivization in languages with the ergative–absolutive case system (see Polinsky, 2005a for a cross-linguistic survey of antipassive constructions). But it should not be inferred from this that the passive is never found in languages with the ergative–absolutive case system; both the passive and the antipassive may occur in the same language (e.g., Basque, Eskimo, and Mam). In the antipassive, the actor argument of the basic two-place predicate remains the (sole) argument of the corresponding antipassive (albeit marked by the absolutive case), with the undergoer argument demoted to adjunct status or, optionally, omitted. If and when expressed, however, the undergoer is marked accordingly by a dative or oblique case. This suggests that the antipassive is as much intransitive or detransitivized as is the passive: a decrease in valency from two (i.e., the actor and undergoer) to one (i.e., the actor) argument. The verb in the antipassive also bears an affix as a marker of valency decreasing. Dyirbal, an Australian Aboriginal language, provides an example of the antipassive (i.e., (5), as opposed to the basic sentence in (4)):

4. Dyirbal

balan	dʸugumbil	baŋgul	yaɽa-ŋgu	balga-n
F-ABS	woman-ABS	M-ERG	man-ERG	hit-NFUT

'The man is hitting the woman.'

5. Dyirbal

bayi	yaɽa	bagun dʸugumbil-gu	balgal-ŋa-nʸu
M-ABS	man-ABS	F-DAT woman-DAT	hit-APASS-NFUT

'The man is hitting the woman.'

In some languages, the demoted original undergoer must be completely eliminated from the antipassive clause. Bandjalang, another Australian Aboriginal language, is one such language, as illustrated in (6) and (7).

6. Bandjalang

mali-yu	ɖa:ɖam-bu	mala-Ø	bulan-Ø	ɖa-ila
that-ERG	child-ERG	that-ABS	meat-ABS	eat-PRS

"The child is eating the meat."

7. Bandjalang

mala-Ø	ɖa:ɖam-Ø	ɖa-le-ila
that-ABS	child-ABS	eat-APASS-PRS

'The child is eating.'

Noun Incorporation

Noun incorporation is another type of valency-changing operation found in some languages of the world, whereby one of the arguments of the predicate becomes part of the

predicate, thereby losing its argument status (Mithun, 1984). The resulting predicate may function as a single word. In Chukchi (a Chukotko-Kamchatkan language), for instance, the vowels of incorporated nouns must participate in word-internal vowel harmony in conjunction with host verbs (i.e., *kupre* in (8) vs *kopra* in (9)):

8. Chukchi

tumg-e	na-ntəwat-ən	kupre-n
friends-ERG	set-TR	net-ABS

'The friends set the net.'

9. Chukchi

tumg-ət	kopra-ntəwat-gʔat
friend-NOM	net-set-INTR

'The friends set nets.'

Note that, with the undergoer incorporated into the predicate, the actor argument of the basic two-place predicate in (8) loses its ergative marking and is instead marked by the nominative case in (9). In Chukchi, noun incorporation also motivates the verb to shed its transitive marking (i.e., *-ən*) in favor of the intransitive marking (i.e., *-gʔat*). These changes indicate that noun incorporation involves reduction of two arguments of the basic predicate to one (i.e., valency decreasing).

Advancement of Adjuncts to Arguments

So far, argument reduction has been illustrated. In many languages, it is also possible to do the opposite, that is, to increase the valency of the basic verb by promoting an adjunct (e.g., beneficiary/recipient, comitative, instrumental, locative, etc.) to argument status. In order to signal such advancement or promotion, the verb is typically marked by a so-called applicative affix; the construction as a whole is commonly referred to as the applicative construction (see Peterson, 2007 for a cross-linguistic survey; also Polinsky, 2005b). In Kinyarwanda (a Niger–Congo language), for instance, instrumental adjuncts can be promoted optionally to argument or direct object status. Compare the following two sentences:

10. Kinyarwanda

úmwáalímu	a-ra-andik-a	íbárúwa	n'í-íkárámu
teacher	he-PRS-write-ASP	letter	with-pen

'The teacher is writing a letter with the pen.'

11. Kinyarwanda

úmwáalímu	a-ra-andik-iish-a	íbárúwa	íkárámu
teacher	he-PRS-write-APPL-ASP	letter	pen

'The teacher is writing a letter with the pen.'

The instrumental adjunct in (10) is promoted to direct object in (11), evidence for which can be adduced from the fact that the instrumental nominal, which is marked by the instrumental prefix in (10), appears as a bare nominal (i.e., no case marking) in (11). This advancement must also be registered on the verb by the applicative suffix *-iish*, as in (11). Both the old direct object (a.k.a. the basic object) and the newly created direct object (a.k.a. the applied object) in (11) exhibit grammatical properties of direct objecthood (but see the section 'Doubling of Grammatical Relations'). This suggests that the valency of the derived verb in (11) is greater by one argument than that of the basic verb in (10). In (10), there are two arguments (i.e., *teacher* and *letter*) and one adjunct (i.e., *pen*). In (11), on the other hand, there are three arguments (i.e., *teacher*, *letter*, and *pen*). Moreover, the argument structure of the predicate in (10) specifies the relation between the actor and the undergoer, and the argument structure of the derived predicate in (11) specifies the relation between the actor, the undergoer, and the instrument. To put it differently, (10), without the instrumental phrase *n'í-íkárámu*, will remain grammatical, whereas (11), with *íkárámu* deleted, will be rendered ungrammatical. Incidentally, the most common semantic role that is encoded by the applied object is that of beneficiary/maleficiary and/or recipient (Peterson, 2007, p. 40).

Causativization

In common with advancement of adjuncts, causativization adds an argument to the argument structure of the basic predicate. However, it does so not by converting an existing adjunct into an argument, but by introducing a completely new argument into the argument structure (see Song, 1996, 2005 for a cross-linguistic survey of causative constructions; but cf. Kittilä (2009) for the non-valency-changing function of causative morphology). This newly introduced argument is the causer argument. Thus, if the basic verb is a one-place verb, the corresponding causative verb will be a two-place verb (the newly added causer argument and the sole argument of the original basic verb). If the basic verb is a two-place verb, the corresponding causative verb will be a three-place verb (three arguments including the causer argument). This is illustrated by the following pair of Turkish sentences. As opposed to the basic verb in (12), the causative verb in (13), with the causative suffix *-t*, has the causer argument, *dişçi*.

12. Turkish

müdür	mektub-u	imzala-dɪ
director	letter-DO	sign-PST

'The director signed the letter.'

13. Turkish

dişçi	mektub-u	müdür-e	imzala-t-tɪ
dentist	letter-DO	director-IO	sign–CS–PST

'The dentist made the director sign the letter.'

The valency of the causative verb thus exceeds that of the basic verb by one argument, as can be neatly expressed in

14. NONCAUSATIVE: n vs CAUSATIVE: $n + 1$
[n: number of arguments]

The schema in (14) indicates that causativization is a case of argument addition (i.e., valency increasing), with the status of the argument(s) of the basic predicate remaining intact. This may indeed be true of one-place verbs; causativization only increases the valency of the basic one-place verb from one to two arguments. Causativization of two- or three-place (or trivalent) verbs, in contrast, would give rise to three or four arguments, respectively, more than many languages may be able to cope with – regardless of whether verbs are basic or derived. Indeed, there is much cross-linguistic variation in causativization of two- or three-place verbs, as opposed to one-place verbs. For instance, there are languages that derive causative verbs only from basic one-place verbs (e.g., Comrie,

1989; Dixon, 2000; Dixon and Aikhenvald, 1997; Song, 2001). Moreover, in some languages argument structure is manipulated in such a way that the valency of the derived verb is prevented from exceeding that of the basic verb (Dixon, 2000; Song, 1996), as will be discussed in the section 'Change of Argument Structure without Change of Valency.'

Change of Argument Structure without Change of Valency

There are languages that introduce a new argument into the argument structure of the causative verb, only if one of the arguments of the basic two- or three-place verb is demoted to an adjunct or omitted completely. In other words, causativization of the basic two- or three-place verb in such languages results in no increase in valency, contrary to the schema in (14), but rather the valency of the derived causative verb is equal to that of the basic verb. In Babungo (a Niger–Congo language), for instance, when the causative suffix *-s* is added to two-place verbs, the direct object of the basic verb must be omitted or expressed as an adjunct. Thus, the original direct object in the noncausative sentence in (15), *zɔ̃*, can either appear as a prepositional adjunct, *nə zɔ̃*, or be omitted in the corresponding causative sentence in (16).

15. Babungo

ŋwə́	fɛ̀e	zɔ̃
he	fear-PERF	snake

'He was afraid of a snake.'

16. Babungo

mə̀	fɛ̀sə̀	ŋwə́	(nə̀ zɔ̃)
I	fear–CS–PERF	him	(with snake)

'I frightened him with a snake.'

There also exist some languages that maintain the canonical number of arguments with respect to verbs or predicates by not encoding either the causee or some argument other than the causer when these verbs are morphologically causativized. In Afar, an Eastern Cushitic language, there are two causative suffixes, one exclusively for intransitive verbs and the other for transitive verbs. Many causativized transitive verbs, unlike causativized intransitive ones, do not have the original subject of transitive verbs (i.e., the causee NP) specified, as in

17. Afar

ʼoson	ʼgarca	gey-siis-ee-ʼni
they	thief	find–CS–they/PERF-PL

'They caused the thief to be found/they caused someone to find the thief.'

So normally, in Afar, the number of arguments per causative verb, regardless of the transitivity of the original verb, is no more than two.

Songhai (or Sonrai), a Nilo-Saharan language, has a causative suffix *-ndi*, which can be added to intransitive and transitive verbs. When it is suffixed to ditransitive verbs, either the causee NP or the indirect object NP of the original verb has to be left out. This explains why the following sentence involving a three-place predicate *neere* 'to sell' is ambiguous in two ways.

18. Songhai

garba	neere-ndi	bari	di	musa	se
Garba	sell-CS	horse	the	Musa	IO

'Garba had Musa sell the horse' *or*
'Garba had the horse sold to Musa.'

In other words, there is a strict requirement in this Nilo-Saharan language that there should be no more than three arguments per causative verb.

Moreover, there are languages that avoid exceeding the maximum number of arguments by drawing on detransitivizing strategies already available in the grammar. In Halkomelem, a Salish language, morphological causativization is possible only if the noncausative verb is first detransitivized via the antipassive suffix *-əm*. Thus, (19) is ungrammatical, since the causative suffix *-st* is added to the transitive verb stem, *q'wəl-ət-*. In contrast, (20) is grammatical, since the transitive verb is antipassivized (i.e., detransitivized) before morphological causativization takes place.

19. Halkomelem

*ni	cən	q'ʷəl-ət-stəxʷ	kʷθə	səplíl	ʔə	łə	sɬéniʔ	
AUX	1SG	bake-TR-CS	DET	bread	OBL	DET	woman	

"I had the woman bake the bread."

20. Halkomelem

ni	cən	q'ʷə́l-əm-stəxʷ	θə	sɬéniʔ	ʔə	kʷθə	səplíl
AUX	1SG	bake-APASS-CS	DET	woman	OBL	DET	bread

'I had the woman bake the bread.'

In Blackfoot, an Algonquian language, there are two causative suffixes, *-ippi* and *-atti*, which apply to both intransitive and transitive verbs. However, when these suffixes are added to them, transitive verbs must first be detransitivized via the suffix *-a:ki*. The net effect of this detransitivization is that the direct object of the original verb is changed to adjunct status and thus left out of the argument system of the verb concerned. Note that in this language, the verb internally records arguments. Conversely, nonrecorded elements are by definition adjuncts or optional elements. After detransitivization of the two-place verb, only the subject is registered in the verb, not the direct object. Only after that is the causative suffix added to the now detransitivized verb, whereby the causer NP can also be registered in the verb as an argument. Thus, only the causer and causee NPs are recorded in the verb. In Blackfoot, therefore, the number of arguments per causative verb never exceeds two owing to the detransitivization. In effect, the number of arguments in causatives is exactly the same as in noncausative (transitive) sentences. Similarly, in Bandjalang, an Australian Aboriginal language, the causative suffix *-ma* can be added to intransitive verbs. However, when they undergo the morphological causativization, transitive verbs must first be detransitivized via the antipassive suffix *-li*.

In Southern Tiwa (a Kiowa-Tanoan language), the causative verb registers only two arguments, that is the causer and the causee NPs. When the causative suffix *-ʼam* is added to transitive verbs, the direct object of the original verb is obligatorily incorporated into the verb

complex (see the section 'Noun Incorporation' for noun incorporation).

21. Southern Tiwa

I-'u'u-kur-'am-ban
1SG.S:2SG.O-baby-hold–CS–PST

22. Southern Tiwa

*'U'ude i-kur-'am-ban
baby 1SG.S:2SG.O-hold–CS–PST
'I made you hold the baby.'

The sentence without incorporation of the direct object of the original verb as in (22) is ungrammatical. In Southern Tiwa, arguments should be registered in the verb complex, while optionally they can appear in full forms as well. Thus, *'u'ude* 'baby' in (22) is intended to be an argument. But as the causative verb has already reached its full capacity of registering the arguments (i.e., the causer and causee NPs), thereby being unable to record the full NP *'u'ude*, the sentence is ruled out as ungrammatical. On the other hand, in (21) the same NP is incorporated into the verb complex, thus effectively making the original verb intransitive. Now, the subject NP of the detransitivized verb and the causer NP associated with the causative suffix *-'am* can be registered in the verb without any difficulty.

What the foregoing data suggest is that, regardless of whether the predicate is basic or derived, languages allow only a certain number of arguments per predicate (i.e., two or three) (for a detailed discussion, see Song, 1996, Chapter 6; also Kemmer and Verhagen, 1994 from a cognitive–linguistic perspective). The net effect of the various grammatical strategies pressed into service to maintain the canonical number of arguments is no change of valency in spite of the introduction of the causer argument, although there may be a change of argument structure between the basic predicate and the derived predicate: addition of the causer argument offset by demotion to adjunct status (or omission) of one of the arguments of the basic predicate.

Another instance of a change of argument structure with no change of valency comes from noun incorporation (cf the section 'Noun Incorporation'). When one of the arguments is incorporated into the verb, the position vacated by that argument may then be usurped by an adjunct, e.g., instrument, location, or even possessor (Mithun, 1984, p. 856–859). In Tupinambá (a Tupi-Guaraní language), the possessor can be promoted to the direct object position when the possessed noun is incorporated into the verb. Compare (23) and (24).

23. Tupinambá

s-oβá a-yos-éy
his-face I-it-wash
'I washed his face.'

24. Tupinambá

a-s-oβá-éy
I-him-face-wash
'I face-washed him.'

In (24), the possessor is represented on the verb by the prefix *s-*, whereas in (23), without noun incorporation, the direct object is *s-oβá* 'his face,' and it is thus registered on the verb by the prefix *yos-*. In Yucatec Mayan (a Mayan language), the argument position vacated by the incorporated direct object (i.e., *če'* 'tree') is taken up by the locative phrase (i.e., *in-kool* 'my cornfield'), the argument status of which is indicated by its loss of the locative preposition (i.e., *ičil*).

25. Yucatec Mayan

k-in-čak-Ø-k če' ičil in-kool
INCMP-I-chop-it-IPFV tree in my-cornfield
'I chop the tree in my cornfield.'

26. Yucatec Mayan

k-in-č'ak-cče'-t-ik in-kool
INCMP-I-chop-tree-TR-IPFV my-cornfield
'I clear my cornfield.'

Doubling of Grammatical Relations

One theoretical issue in argument addition concerns the question of whether or not identical coding of nominals entails doubling of grammatical relations. In some languages, two nominals in the causative construction may be coded identically, for instance. In Kinyarwanda causatives, both the actor argument (or subject) and the undergoer argument (or direct object) of the basic predicate are coded identically as direct objects. Comrie (1989) interprets such identical coding to be indicative of doubling of the direct object. This position, however, has been challenged by Polinsky (1994), who demonstrates that the two identically coded nominals in Kinyarwanda causatives behave differently in terms of syntactic properties. In fact, only one of the identically coded 'direct objects' is syntactically a direct object, the other being an indirect object, identical coding notwithstanding. Kozinsky and Polinsky (1993) describe more or less the same situation in Korean and Dutch causatives. Similarly, the basic object and the applied object in the Kinyarwanda applicative sentence (11) are bare nominals (that is, coded identically) (see the section 'Advancement of Adjuncts to Arguments' for applicative constructions). This also led to a controversy as to whether or not (11), as opposed to (10), has two direct objects, i.e., doubling of the direct object. Gary and Keenan (1977) take the view that (11) has two direct objects. Perlmutter and Postal (1983), on the other hand, argue that (11) does not have two direct objects, but rather one direct object and one indirect object. Further evidence against doubling of the direct object in Kinyarwanda applicative constructions is provided by Dryer (1983) and Polinsky (1994). Peterson (2007) provides a cross-linguistic survey of the distribution of direct object properties in applicative constructions. His preliminary generalization is that when the newly created or applied object in applicative constructions encodes semantic roles other than beneficiary/recipient (i.e., instrumental, locative, comitative, etc.), it tends not to display all direct object properties with the old or basic object claiming some direct object properties. If the encoded semantic role is beneficiary/recipient, however, the tendency is that the applied object possesses direct object properties, with the basic object displaying direct object properties only in a few attested instances.

Theoretical Approaches to Valency-Changing Operations

Current grammatical theories have proposed different approaches to representation of valency-changing operations; more than one approach may also be possible within one and the same grammatical theory (Brown and Miller, 1996). These approaches can be characterized broadly as lexical or syntactic. Lexical Functional Grammar regards valency-changing operations as productive lexical processes giving rise to alternative assignments of grammatical functions (or grammatical relations) to arguments. Relational Grammar invokes revaluation rules to handle valency-changing operations. These revaluation rules are regarded as syntactic, because they operate on grammatical relations between initial and noninitial strata (or different syntactic levels) of the relational structure. In Principles and Parameters Theory, valency-changing operations are treated as syntactic. In morphological causativization, for instance, the basic verb undergoes movement to combine with the causative affix at an abstract syntactic level. This movement is then claimed to comply with the same principles that are obeyed by other movements in syntax. Research interest in valency-changing operations, however, has all but dissipated in Minimalism, the latest generative perspective on linguistic theory. This may not come as a surprise because the primary objective of Minimalism is to evaluate theories such as Principles and Parameters Theory in terms of metatheoretical desiderata (e.g., virtual conceptual necessity, economy, symmetry) rather than develop any particular theory.

Abstract

We distinguish two broad categories of value theories, objective and subjective, which focus, respectively, on the conditions of production and on the preferences of consumers. We discuss the contributions to the labor theory of value made by David Ricardo and Karl Marx, outline some criticisms of Marxian value theory, and summarize Piero Sraffa's attempt to rehabilitate the classical, objective theory of value. We then outline the development of the marginal utility of value and discuss its relationship to market equilibrium, before assessing the marginal productivity theory of distribution, some extensions to utility analysis, and the connection between utility and welfare.

Introduction

We distinguish two broad categories of value theories, objective and subjective, which focus, respectively, on the conditions of production and on the preferences of consumers. While thinking on the issue can be traced back at least as far as Aristotle (Lowry, 1987), modern work on the objective value theory was most influential in the era of classical political economy, especially in the work of David Ricardo (1772–1823) and Karl Marx (1818–83), and was revived after 1960 by the followers of Piero Sraffa (1898–1983). Subjective value theory became prominent after 1870 under the influence of William Stanley Jevons (1835–82), Léon Walras (1834–1910), and Carl Menger (1840–1921), and remains the approach to the theory of value that is taken by mainstream economists today.

The Objective Classical Theory of Value

The objective classical theory of value dates from the mid- to late seventeenth century, reflecting increased interest in the production of commodities and reduced emphasis on the circumstances of their exchange. It was the cornerstone of classical political economy (Dobb, 1973; O'Brien, 2004). In the two decades after 1670, Sir William Petty (1623–87) "came remarkably close to the idea that the exchange value of a commodity is determined by the quantity of labour needed to produce it" (Meek, 1973, p. 35). Half a century later, Richard Cantillon (1680–1734) distinguished the market price of a commodity from its 'intrinsic value,' the latter being proportional to the land and labor needed for its production.

In *The Wealth of Nations* (1776), Adam Smith (1723–90) took three distinct approaches to the problem of value. The first, following Petty, was a simple 'labor embodied' theory, which Smith believed to apply without qualification to the 'early and rude state of society.' The second, which he thought more appropriate to contemporary capitalism, was an 'adding-up theory' that explained value as the sum of the costs of production, including land and capital in addition to labor. His third theory, in some ways which anticipated the later subjective value theory (but was not fully developed by Smith), saw value as being determined by the 'toil and trouble' experienced by the producers.

David Ricardo and the Labor Theory of Value

A much more systematic treatment of value was provided by David Ricardo. Ricardo's primary interest was in the distribution of the social product, and in particular the determinants of the rate of profit, since he regarded this as by far the most important influence on the growth prospects of the British economy. He needed a theory of value less for its own sake than to provide a reliable way of measuring these distributional variables. Ricardo seems originally to have hoped that he could evade the problem by formulating a 'corn model' of agricultural production in which both inputs and outputs consisted entirely of physical quantities of grain. Soon, however, he replaced corn with labor "as the quantity in terms of which product, wages, and surplus were alike expressed" (Dobb, 1973, p. 74).

Ricardo was critical both of Adam Smith's 'adding-up theory' of value and of Jean-Baptiste Say's subjective approach to the problem. He began his own *Principles of Political Economy and Taxation* with an extended discussion of the labor theory of value, noting that air and water were much more useful than gold, but also much less valuable. "Utility then is not the measure of exchangeable value," he concluded as a general principle, "although it is absolutely essential to it" (Ricardo, 1821, p. 11). For the small minority of useful objects that could not be freely reproduced, such as rare statues and pictures, scarce books and coins, and vintage wines, value is indeed determined by their scarcity relative to the demand for them. But the great majority of commodities can be freely reproduced 'almost without any assignable limit' by the employment of human labor, and the labor theory of value does apply to all such commodities, "on the production of which competition operates without constraint" (Ricardo, 1821, p. 12). Fluctuations in supply and demand cause only "accidental and temporary deviations of the actual or market price of commodities" from their 'primary and natural price,' which is given by "the comparative quantity of labor which is necessary to their production" (Ricardo, 1821, p. 88).

Integrated with his labor theory of value was Ricardo's surplus theory of income distribution. Wages were determined

by the consumption requirements of the laborers, and were the first charge on the net product (the difference between total output and the means of production – seed corn, for example – that were needed to produce it). The residual was the 'surplus produce,' which Ricardo believed to be divided between capitalists and landlords in accordance with his theory of differential rent. His treatment of rent allowed Ricardo (unlike Cantillon) to eliminate land from the analysis of value, since the value of corn was determined by the quantity of labor needed to produce it on the least fertile land, where no rent was paid.

Capital, however, was altogether more troublesome. It posed four difficult problems, all related to the question of time (O'Brien, 2004, p. 100). First, the ratio of capital to labor differed from industry to industry. Second, the durability of fixed capital – which Ricardo distinguished from circulating capital – was unequal between industries. Third and fourth, the period of production and the turnover rate of capital were also different in different industries. These four factors would cause prices to diverge from labor values, even in the long period when rates of profit tended toward equality, so that an increase in wages would lead to changes in natural prices even if the quantities of labor embodied in the various commodities was unaltered. But Ricardo convinced himself that these complications were relatively minor. "The greatest effects which could be produced on the relative prices of those goods from a rise in wages," he claimed, "could not exceed 6 or 7 per cent" (Ricardo, 1821, p. 36), leaving him with what the neoclassical economist George Stigler (1958) famously described as a 93% labor theory of value.

Ricardo continued to wrestle with these problems until the very end of his life, acknowledging just before he died that the labor theory of value was only an approximation to the truth (King, 2013, pp. 79–80). But that did not lead him to embrace a subjective theory of value, or even to withdraw his objections to Adam Smith's adding-up theory. A change in wages would not lead to a change in the prices of all commodities in the same direction, as Smith's principle entailed. 'On the contrary,' Ricardo noted, "if wages fell, those commodities only would fall in value, which had a less proportion of fixed capital employed upon them, than the medium in which price was estimated [that is, gold]; all those which had more, would positively rise in price" as a consequence of the increased rate of profits (Ricardo, 1821, p. 46).

Karl Marx and the Labor Theory of Value

Marx was a strong admirer of Ricardo, but also a severe critic. His most fundamental objection was that Ricardo had failed to distinguish different modes of production, instead regarding capitalism as timeless and eternal. Where the theory of value was concerned, Marx believed, the crucial distinction was between capitalism and the earlier, classless 'simple' or 'petty commodity production.' In simple commodity production, commodities normally sold at prices equal to their labor values, but in capitalism matters were considerably more complicated.

He also criticized Ricardo for failing to make a second vital distinction, between constant and variable capital: the former was the value of the 'dead' or 'stored-up' labor in raw materials and machines, while the latter, the 'living labor,' represented the value of the workers' labor power, and was the sole source of surplus value, and hence of profit. This affected his analysis of the rate of profit, which for Marx (no less than for Ricardo) was the single most important economic variable. In Marx's system, the rate of profit was positively related to the rate of exploitation (the ratio of surplus value to variable capital) and negatively related to the organic composition of capital (the ratio of constant to variable capital) (Marx, 1867: chs. VIII–IX; Marx, 1895: chs. III–IV; Howard and King, 1985: ch. 6).

In a competitive capitalist economy, Marx argued – again like Ricardo – there would be strong forces tending to equalize both the rate of profit and the rate of exploitation in all industries. But there were inescapable technical conditions that gave rise to large differences in the organic composition of capital in different sectors. This meant that commodities would not, in general, sell at prices equal to their labor values. They would instead sell at what Marx termed 'prices of production,' which would exceed labor values in industries with an above-average organic composition and fall below values if the organic composition was below the social average. In aggregate, however, the sum of prices would equal the sum of values; the sum of profits would be equal to the sum of surplus value; and the rate of profit would be the same, whether it was calculated in terms of values or prices of production.

In the numerical example in volume III of *Capital*, published in 1895, 12 years after Marx's death, there are five industries, with an organic composition of capital ranging from 1.5 in industry III to 19.0 in industry V, and also significant differences between industries in the durability of constant capital. After transformation, the ratio of price of production to labor value ranges from 1.85 in industry III to 0.86 in industry V (Marx, 1895: ch. IX). This analysis, to repeat, did not appear in Marx's lifetime, and before its publication Friedrich Engels (1820–95) amused himself by announcing a 'prize essay competition' in which he invited the readers of volume II of *Capital* to supply the solution to the so-called 'transformation problem.' No one succeeded, though several entrants came very close (Howard and King, 1985, 1989: part III, ch. 2).

Criticism of Marx's procedure for transforming labor values into prices of production began almost immediately after it was revealed in 1895. The Austrian economist Eugen von Böhm-Bawerk (1851–1914) rejected the entire theoretical apparatus, including the distinction between constant and variable capital and the theory of exploitation in addition to the labor theory of value itself, while his former student Rudolf Hilferding (1877–1941) came to Marx's defense. Ladislaus von Bortkiewicz (1868–1931), himself sympathetic to the classical tradition in political economy, took issue with the details of Marx's analysis, criticizing him for failing to transform input values and pointing out that the aggregate equalities on which Marx had insisted would hold only under special circumstances (all three essays are reprinted in Sweezy, 1975). Other significant contributors to the pre-1914 debate included Wolfgang Mühlpfort (1872–1928) and V.K. Dmitriev (1868–1913) (Howard and King, 1989: ch. 3).

In the 1920s some Marxists began to ask whether these quantitative aspects of the labor theory of value had not been given too much attention, at the expense of the deeper and more interesting qualitative questions. The best known of these Hegelian Marxists was the Russian Menshevik, Isaak Illich

Rubin (1886–1937), whose thinking has stimulated a large and continuing literature on the 'form of value' in Marx (Rubin, 1973). Some Western Marxists began to ponder the implications of the decline in competition associated with the rise of cartels, trusts, and giant corporations at the end of the nineteenth century. If competition was no longer strong enough to equalize the rate of profit across industries, what relevance did the (quantitative) labor theory of value have in the new stage of 'monopoly' or 'state monopoly capitalism'? Paul Sweezy (1910–2004) borrowed extensively from neoclassical analyses of oligopoly pricing, while continuing to endorse the qualitative labor theory of value (Sweezy, 1942). Discussion of the (quantitative) transformation problem also continued after 1945, with a range of alternative solutions being proposed (Howard and King, 1992, part IV).

Piero Sraffa and the Revival of the Classical Theory of Value

Meanwhile, a young Italian scholar was working in Cambridge on the definitive edition of Ricardo's collected works, and also attempting to reinterpret the entire classical tradition in value theory. The eventual outcome was a slim volume entitled *Production of Commodities by Means of Commodities*, with the modest subtitle 'Prelude to a critique of economic theory.' Piero Sraffa (1898–1983) took as given the outputs of the various commodities, the inputs of those commodities and of labor that were needed to produce them, and one distributive variable. This could be either the real wage (as in Ricardo), or the wage share in net output, or – Sraffa's own preference – the rate of profit, itself possibly determined by the rate of interest. He demonstrated that, on the assumption of an equal rate of profit in all industries, these parameters were sufficient to determine all prices and the other distributive variables, without any reference to demand conditions or to marginal utilities (Sraffa, 1960).

In fact Sraffa shared the classical emphasis on 'physical real cost' (Kurz, 2003, p. 169), and had no time whatever for subjective value theory. His analysis pointed to fundamental weaknesses in the neoclassical theory of capital, since the capital stock could not be defined independently of the rate of profit, still less inserted into an aggregate production function that could then be differentiated with respect to 'capital' in order to determine the rate of profit. Sraffa also exposed a 'monotonic fallacy' in neoclassical theory: a rise in the profit rate, he demonstrated, might reduce the value of capital (the phenomenon of 'capital reversal') and might also induce capitalists to adopt productive techniques with a higher capital–labor ratio ('reswitching'). Sraffa's work encouraged the search for alternatives to the marginal productivity theory of distribution and gave rise to the celebrated 'Cambridge controversies' in the theory of capital (Harcourt, 1973).

There were also important implications for the Marxian labor theory of value. Sraffa's intention seems to have been to rehabilitate Ricardo's value theory ('seems,' because he published almost nothing after 1960 and never responded to the substantial critical literature that his book soon generated). But Meek (1973, pp. xxviii–xliv) soon recognized that Sraffa's analysis could also be used to solve the transformation problem. Sraffa had devised a 'Standard Commodity' in which the ratio of outputs to inputs was identical for all commodities. This Standard Commodity, Meek suggested, could be used as the *numéraire* in transforming values into prices of production, overcoming the difficulties that Bortkiewicz and others had identified with Marx's solution, so that (as in the one-commodity Ricardian corn model) the maximum rate of profit depended solely on the technical conditions of production and did not vary with prices or with the actual rate of profit.

This procedure might be sufficient to rescue the labor theory of value. Whether it was also necessary was another matter. Neoclassical critics like Paul Samuelson (1915–2009) maintained that the entire process of transformation was an 'unnecessary detour,' since prices of production could be derived directly from knowledge of conditions of production and income distribution, without any need to calculate labor values. Samuelson was supported by the former Marxist Ian Steedman (b. 1941), who also drew on Sraffa to identify serious additional problems with the labor theory. The existence of joint production and alternative techniques of production could produce paradoxical results, including negative labor values and negative surplus value, even while prices and the rate of profit remained positive (Steedman, 1977). It was soon recognized that these perverse outcomes posed a significant challenge, not just to Marxian value theory but also to any Sraffian rehabilitation of classical theory (Howard, 1987).

As already noted, Sraffa's own intentions were never made clear. The fundamental question that he left unanswered was whether *Production of Commodities* should be regarded as a brick or a broom, that is to say, as the basis for a modernized version of classical value theory or only as a critique – certainly, a profound and damaging critique – of the subjective, neoclassical theory of value and distribution. Thus his work remains open to a variety of different, if not entirely inconsistent, interpretations (Roncaglia, 2009).

One final question concerns the ethical dimension of objective value theory, and in particular the use of labor values as instruments for the purposes of socialist planning. It is unclear what Marx's own position was on this issue (compare Meek, 1973, pp. 256–263 and Robinson, 1942, pp. 23–24). Several serious problems have been identified, including the environmental damage caused by neglecting the costs of land, water, and other natural resources; the excessive capital-intensity induced by ignoring differences in the durability of capital goods; and the failure to relate prices to use values when there is no genuine market for consumer goods (Nove, 1983). Arguably, efficient planning requires a synthesis of objective and subjective value theory, as proposed (unsuccessfully) in the former Communist countries by would-be reformers like Viktor Novozhilov (1892–1970) and Ota Šik (1919–2004).

The Subjective Neoclassical Theory of Value

In the years following the publication of William Stanley Jevons's *Theory of Political Economy* (1871), Carl Menger's *Grundsätze der Volkswirtschaftslehre* (1871), and Léon Walras's *Élements d'Économie Politique Pure* (1874), the concept of 'marginal utility' gravitated to the very center of economic

theory. While there were many important classical precursors to significant elements of 'neoclassical' theory (Ekelund and Hébert, 2002), the 1870s marked a turning point because the entire body of theory started to be systematically reformulated around the proposition that the value of economic goods is fundamentally a consequence of subjective assessment by individuals.

Marginal Utility and Equilibrium

The utility that an individual derives from the consumption of a quantity of a particular good is determined by his or her subjective assessment of the pleasure, or satisfaction, derived from consumption. 'Marginal utility' refers to the satisfaction that an individual gains from the consumption of an additional unit of a particular good in a given context. For example, the context for the marginal utility derived from the consumption of the 10th unit of a good is given by the individual having already consumed 9 units of that good, and so on. While H.H. Gossen (1810–58) and Jules Dupuit (1804–66) had already posited that marginal utility diminishes with additional consumption, the early neoclassical economists reflected on the implications of that proposition for the relationships between demand and price, and supply and price.

Of the three founders of the marginal revolution, Menger's contention that "value does not exist outside the consciousness of men" (Menger, 1871, p. 121) was the strongest endorsement of a strictly subjective character of value theory. His consequential treatment focused on causal sequences and inspired the development of an 'Austrian school' that was distinct from the mainstream equilibrium analysis associated with Jevons and Walras, where, to varying degrees, objectively determined supply considerations equilibrate with the subjectively determined demand within a competitive environment on the assumption that individuals choose to maximize their utility. The central pillar of their theory is the proposition that a maximizing individual will attain equilibrium through exchange when the relative prices for goods possessed are equal to his or her subjective assessment of their relative marginal utilities. If the relative price of a good is less than an individual's assessment of its marginal utility relative to other goods, a maximizing individual will wish to acquire more of that good in exchange for other goods he or she possesses with relative prices that are higher than his or her assessment of their relative marginal utility.

From this, three key principles emerged: quantity demanded for a particular good decreases with respect to the price of that good; quantity supplied for a particular good increases with respect to the price of that good; and, when one equilibrium price prevails for each particular good (the 'law of one price') in a competitive environment, quantities of goods are exchanged up to the point where each individual's assessment of relative marginal utilities reflects relative equilibrium prices, at which point the value of all goods supplied is equal to the value of all goods demanded for both individuals and markets. Some early neoclassical economists used these relationships to reinterpret Adam Smith's discussion of the distinction between use value and exchange value to suggest that water has a low exchange value because its relative abundance suggests low marginal utility, whereas diamonds have a high exchange value because their relative scarcity suggests high marginal utility. Conversely, the high total utility of water is equated with high use value, whereas the low total utility of diamonds is equated with low use value.

The general conception of equilibrium was formulated by Léon Walras by treating utility for each individual as 'separable,' so that the utility from consuming a good depends on the quantity of that good alone, and 'additive' in the sense that total utility from consuming a number of goods is derived by summing of utility for each good. If a, b, … , m indicate quantities of economic goods A, B, …, M held by individual i following voluntary exchange, individual i's total utility U is

$$U_i = f(a_i) + g(b_i) + \ldots + r(m_i) \qquad [1]$$

The marginal utilities of each good are given by the first derivative of the respective separable elements of relation [1], so that relative prices under competitive equilibrium reflect the various ratios of these first derivatives. However, in general equilibrium the quantity demanded of any one good is not just related to the price of that good; rather, it is related to the equilibrium price for each and every consumer good, with each equilibrium price expressed as the rate at which it exchanges for a common *numéraire* (good A). But the relationship between the price of each particular good and the quantity demanded of each good remains negative; it is just that the demand relationship is conditioned by the relative prices of other consumer goods.

Walrasian equilibration extends beyond exchange to encompass production and capital formulation. Walras also argued that a 'groping' process of price adjustments, which he called *tâtonnement*, would lead to a system of equilibrium prices, to which quantities would adjust until markets fully clear. From the perspective of value theory, the key point for Walras was that marginal utility, or *rareté* as he called it, was the cause of value due to the general interdependence deriving from the utility-maximizing behavior of each individual entrepreneur, capitalist, landlord, and worker. An entrepreneur making decisions about the formation of a particular capital good has regard to the demand for the productive service provided by that good, as well as the costs of accessing capitalists' savings, just as an entrepreneur purchasing productive services has regard to the demand for consumer goods derived from the theory of exchange, as well as the price of productive services. The direction of causation for all values originates from the relative prices of consumer goods, which reflect relative marginal utilities.

In 1889 Francis Ysidro Edgeworth (1845–1926) was the first to point out a consistency problem with Walras's equilibrating notion of *tâtonnement*, as a static theory does not demonstrate a path from disequilibrium to equilibrium, which is significant when dynamic adjustments to disequilibrium prices take time to complete. For example, disequilibrium decisions concerning the formation of heterogeneous capital goods have flow-on effects for the supply of productive services and the availability of consumer goods. Late in life, Walras removed disequilibrium trading from his theory, with an auctioneer crying out prices but transactions themselves not settled until equilibrium prices have been attained. In

contrast, Vilfredo Pareto (1848–1923), Walras's successor in Lausanne, distinguished between complete and incomplete equilibrium, and provided for the owners of particular capital goods, among others, to acquire positive or negative rents under incomplete equilibrium.

Alfred Marshall (1842–1924), a second-generation neoclassical economist, created an alternative approach to Walras's that has become known as partial equilibrium. By invoking an 'other things being equal' assumption, Marshall developed a theory of the relationship between price, quantity demanded, and quantity supplied, for a particular good in isolation from other goods. For the individual, and the market for a particular good in aggregate, a rise in price leads to a decrease in the quantity demanded; and equilibrium within a market is given at the point where the demand and supply intersect.

In Marshall's analysis, the 'marginal demand price' is a point on the demand curve and represents the amount of money that an individual forgoes to acquire one additional unit of the good. Consequently, the marginal demand price is a monetary representation of marginal utility, provided that the marginal utility of money is constant. Pareto objected that this is an unnecessary assumption, and derived the equation for a negatively sloped demand curve when permitting the marginal utility of the money (Walras's *numéraire*) to vary (Pareto 1893–94). In 1915, Eugen Slutsky (1880–1948) then used Pareto's demand equation to isolate the income effect of a price change (the change in the purchasing power of a consumer's budget resulting solely from a change in the price of a good) from the substitution effect (the substitution of one good for another attributable solely to the change in the relative price of the good). In 1934 J.R. Hicks (1904–89) and R.G.D. Allen (1906–83) independently developed an alternative formulation of the income and substitution effects, with Hicks, in *Value and Capital* (1939), subsequently pointing out that the 'Marshallian' demand curve shows the combined influence of the income and substitution effects, whereas a study of the pure effect of changes in relative prices would derive the demand curve based only on the substitution effect by compensating the consumer for any income effect associated with a change in the price of a good. In doing so, Hicks provided a succinct mechanism to reconcile the fundamental difference in the demand theories of Walras–Pareto and Marshall.

Marginal Productivity and the Distribution of the Product

The implication of the theories of production and capital formation for the distribution of the product were not fully articulated in the 1870s. For example, Walras's theory of production was initially predicated on 'fixed' coefficients of production. It was not until the technique of production was subject to change that questions related to the substitution of different services of production, and to the relationship between such substitution and variations in wage rates and rentals on capital and land, that analysis of the distribution of product, in the form of income, took center stage in the 1890s. Major studies in that regard include the article by J.B. Clark (1847–1938) on 'Distribution as determined by a law of rent' (1891); the influential book by Phillip Wicksteed (1844–1927) *An Essay on the Co-ordination of the Laws of Distribution* (1894); and the 1894 review of that book by A.W. Flux (1867–1942), which simplified and crystallized the meaning of Wicksteed's work by famously invoking Euler's theorem. J.B. Clark's (1899) book, the *Distribution of Wealth*, is also important for bringing the complete story together.

To maximize profit, entrepreneurs reflect on the productivity of each productive service when offering a price for that service, just as the owners of each productive service have regard to the best price they can obtain for providing that service. In the same way that consumers maximize utility by focusing on comparative marginal utilities under competitive conditions, so too would entrepreneurs maximize profits, and the owners of productive services maximize incomes, when the price of productive services reflects their comparative 'marginal product' (the increase in output from adding one final unit of that particular productive service while holding the quantity of all other services unchanged), provided of course that those services are used to produce goods that are the most highly valued by consumers. In such circumstances, Euler's theorem confirms that total product is completely allocated to the owners of productive services in direct proportion to the product of their productive service's marginal product and quantity.

But the limits within which the 'marginal productivity theory of distribution' is valid have been the subject of much discussion, even among early neoclassical economics (Pullen, 2010). Pareto used first-order homogeneous production functions in 1894 to consider the substitution of productive services by changing the coefficients of production, but when he subsequently treated the issue of marginal productivity at length he raised concerns about the limits of substitutability (as some factors are necessarily fixed) and noted that productive services are not independent of output (when there are economies or diseconomies of scale). He also convinced Barone and Wicksteed of the importance of these limitations, with Wicksteed subsequently abandoning much of the marginal theory of distribution. Walras, in contrast, quickly adopted the marginal productivity theory of distribution.

Extended Dimensions to Utility Analysis

The utility relation [1] referred to earlier is only additive because it is separable and expressed as a cardinal quantity. Second-generation neoclassical theorists, however, soon questioned both these requirements, with separability in particular seen as an unnecessary restriction that constrained the scope of utility analysis. In 1889, Rudolf Auspitz (1837–1906) and Richard Lieben (1842–1919) presented the utility of one commodity as depending on the quantities of all commodities, so that the separable and additive utility for individual i given by relation [1] is effectively replaced by a general nonseparable and nonadditive relation, such as relation [2] below:

$$U_i = f(a_i, bi, \ldots m_i) \qquad [2]$$

This allowed Auspitz and Lieben to undertake pioneering theoretical work on the complementary or substitutable relationship between different goods, which was later adopted and extended by Edgeworth, Pareto, and others.

But the extension of the analysis to encompass demand derived from multi-good utility functions also posed serious questions regarding the stability of the utility relation. When utility at a particular point in the utility system alters, depending on the path taken to attain that point, demand relationships will fluctuate. Utility is no longer completely exogenous – some elements of an individual's subjective valuation of utility, and the associated demand relationships, are influenced by the economic process itself. Stable demand equations depend on each individual's assessment of utility being 'path independent,' so that utility at a particular point is the same irrespective of the path to that point. In mathematical terms, path independence is contingent upon establishing the 'integrability' of the utility function, sometimes referred to as the 'integrability problem.' The formal conditions that establish integrability for economic analysis were first devised in Italian by G.B. Antonelli (1858–1944) in 1886, but their importance was not appreciated at the time. Nicolas Georgescu-Roegen (1906–94), Herman Wold (1908–92), and Paul Samuelson subsequently provided formally correct solutions.

The second significant change to utility theory was the move away from specifying utility as a quantity (cardinal utility) toward preferences over particular combinations of goods (ordinal utility). After Irving Fisher (1867–1947) conjectured, in 1892, that the measurement of utility may not be strictly required for equilibrium theory, Pareto (1900, 2006–09) demonstrated analytically that the shape of Edgeworth's indifference curves is unchanged for an individual irrespective of whether utility is considered cardinally or ordinally, and that the point of economic equilibrium is identical in both cases. He then suggested that experimental data on choice between pairs of goods could be collected in two ways: by direct observation of actual market decisions to derive what Hicks and Allen (1934) would call the marginal rates of substitution (which play the same role as relative marginal utilities in early neoclassical theory), or by conducting a series of binary choice experiments to notionally derive indifference curves after establishing whether respondents reject or accept proposed transactions. The subsequent and definitive specification of choice theory replaced the indifference curve framework with axiomatic formalism when Paul Samuelson (1938) and Hendrik Houthakker (1950) respectively introduced the 'weak' and 'strong' axioms of 'revealed preference.' One feature of the 'strong axiom' is that it establishes conditions for preference revelation that are consistent with integrability having been established for demand relationships and utility.

Utility and Welfare

While Marshall and Edgeworth took important tentative steps in the direction of analyzing the relationship between individual utility and collective welfare, it was Pareto who argued that any suggestion that individual maximization necessarily implies collective economic maximization is a proposition that needs to be demonstrated analytically. In demonstrating that relationship with the aid of his famous welfare criterion (that an unequivocal gain in collective economic welfare requires at least one person to gain and no one to be made worse off), Pareto (1906–09) also underlined his view that interpersonal comparability of utility must be excluded from economic theory generally, and from the analysis of collective economic welfare in particular. However, Pareto (1913) also introduced a formal analysis of social welfare by including arguments pertaining to the welfare of other members of the collective within each individual's utility function. This necessarily presumed that each individual person in society makes interpersonal comparison of utility and, as such, opened the possibility for analysis of redistribution in particular and social welfare more generally. But in extending the scope of the utility function in such a way, Pareto himself abandoned both his own welfare criterion and the use of ordered preferences (relying instead on quantities of utility). Ever since, however, the economic approach to social welfare has been subject to repeated attempts to reinsert both the Pareto criterion and the Paretian preference ordering back into the analysis of social welfare. The works of Abram Bergson (1938) and Kenneth Arrow (1950) are two of the more prominent examples.

Conclusion: Value in a Digital Age

One final problem is specific to the digital age. How does objective value theory apply in cyberspace? What, exactly, does Twitter produce? Which of its employees are productive laborers, which are unproductive, and why? Given that the marginal quantity of labor embodied in the 'product,' whatever that might be, is very close to zero, while the average quantity of labor is very much larger, what is the relevant quantity for the purposes of defining value? Given the importance of intellectual property and hence of 'intangible' or 'fictitious capital' (Marx's phrase) in the digital economy, is there any tendency for the rate of profit to be equalized across the economy? How would Marx – or for that matter Ricardo – have reacted to a world of temporary monopolies, protected by intellectual property laws but subject to constant erosion by new technologies of production and consumption? The difficulties posed by these questions seem rather less damaging to the subjective than to the objective theory of value.

Abstract

For practical purposes placing an economic value on life is straightforward. People make tradeoffs between small changes in their probability of survival and finite amounts of valuable time and money. Estimates of these values of changes in mortality risks, or values of statistical lives, come from analysis of jobs, consumption, and direct questioning. Evidence indicates typical values for adults are from $2 million to $12 million (2011 US dollors). Heterogeneity is expected rather than a single, universal value. Evidence that values are lower for seniors is mixed, but for young children values are 1.5–2.0 times higher. Altruism can be relevant and is greatest for children in the household. These theoretically preferred values have mostly displaced cost-of-illness. Gradual displacement of quality-adjusted life years for valuing changes in length of life has facilitated moving beyond cost effectiveness analysis. Deontological and estimation issues aside, economic values of life based on tradeoffs are likely to continue to be useful in policy decisions.

Thinking about the Economics of Value of Life

The economics of the value of life is about what individuals and societies are willing to sacrifice to get longer expected lifetimes. Value of life is about private choices that individuals make implicitly and explicitly about their own health and safety. Value of life is also about collective, public choices that societies make concerning expenditure, tax, and especially regulatory programs that affect mortality risks. Inferences from individual choices inform public decisions about such things as traffic safety and air quality regulations and are a vital input into benefit–cost analysis. Although ethical and estimation concerns exist, these values are useful in policy decisions about health, safety, and the environment.

The Term 'Value of Life'

Value of life typically refers to monetary values of things that individuals are willing to trade for small changes in probabilities of their own survival. These situations are typically what individuals face in life and what decision makers face in making public policy. Value of life is about tradeoffs involving small changes in risk; it is not about willingness to pay to avoid certain death.

Value of a Statistical Life

The typical situation is illustrated by thinking about an individual who is one of a group of 10 000 people. Everyone in the group is identical and knows that during the next year nine people in the group will die. Everyone also knows that the number of people who are going to die could be reduced to eight if sufficient funds can be raised. If somehow it is known that each individual is willing to pay $600 for the reduction of one death in the group, then the value of life is $600 per person times 10 000 people, or $6 million. Sometimes this amount is referred to as the 'value of a statistical life' (VSL) because the identity of the individual who would have been the ninth death, yet lives, is unknown at the beginning of the period when the decision is made.

Value of a Change in Mortality Risk

The numerical example illustrates another way of interpreting value of life. The reduction in the number of deaths implies that the probability of death faced by each individual decreases from 0.0009 to 0.0008. The $600 that the individual is willing to pay reduces the probability of his or her death by 0.0001. Because information is available from similar situations with small changes in the risk of death, but the changes are not exactly the same, for convenience, the value is standardized to a unit change (1–0). The standardized 'value of a change in mortality risk' is $600 times the 10 000 needed to standardize 0.0001 to 1, or $6 million. Both the 'value of a statistical life' and the standardized 'value of a change in mortality risk' represent what is typically meant by value of life. It is the rate at which individuals are willing to trade small amounts of money and risk.

Characteristics of Values of Life, Values of Changes in Mortality Risks

The nature of value of life as defined above can be described further by considering a simple equation of individual expected utility. Let

$$E(U) = PU(C) \qquad [1]$$

where $E(U)$ is expected lifetime utility for an individual. U is a well-behaved utility function with marginal utility $U'>0$ and diminishing marginal utility $U''<0$. C is consumption and P is the probability of survival. Differentiating eqn [1] keeping the individual at the same level of $E(U)$, and solving for $\mathrm{d}C/\mathrm{d}P$ yields the rate at which the individual is willing to trade off current consumption for a small change in the probability of survival:

$$-\mathrm{d}C/\mathrm{d}P = U(C)/PU' \qquad [2]$$

Equation [2] says that the (negative of the) rate at which an individual is willing to trade consumption for a small change in mortality risk equals the utility of consumption divided by the expected marginal utility of consumption. The amount is positive because the tradeoff itself is negative, i.e., less C for more P. If consumption is expressed in monetary terms, U' is the marginal utility of income, and PU' would be expected marginal utility of income. This would mean that the value of a change in mortality risk, $-dC/dP$, would be the expected monetary value of the utility of consumption; it is willingness to pay for risk reductions. For small changes eqn [2] suggests that it makes little difference whether the individual is paying for small reductions in mortality risk or accepting compensation for small additions to mortality risk. For example, for small, equal (and opposite) changes in mortality risk, the amount the individual is willing to pay for a slightly safer job is approximately the same as the amount the individual is willing to accept for a job which is slightly riskier.

While the simple equation above captures the essence of the risk-dollar tradeoff, formal models of consumer and worker behavior include behavior which affects the probability of survival, budget constraints, insurance, workers' compensation, bequests, multiple periods, multiple risks, and risk perception. See Jones-Lee (1976), Rosen (1981), Cropper and Freeman (1991), and Freeman (2003).

Labor Earnings

Within the context of intense interest in economic growth and national income accounting and from an emphasis on manufacturing and machinery following World War II grew an appreciation for the potentially high returns from investment in human beings. In a special conference issue of the *Journal of Political Economy*, Mushkin (1962) articulated the case for investment in human beings through promoting better health. She argued that the return would be through future increases in labor earnings. If one more person were to live because of an investment in health, then national income would be greater by the amount that person would earn in the labor market. Expected future labor earnings became a standard measure of the value of life. Notwithstanding the fundamental contribution made by establishing human health as an important factor in economic growth, eqn [2] yields no clear, precise connection between the value of life and labor earnings. P may be close to 1, and C may be positively related to labor earnings, but the primary difference is that the value of $U(C)$ is not likely to equal C. Assuming that $U(C)$ equals C means that no allowance is made for either consumption which occurs outside the formal market or for the value of living. Instead, in eqn [2] what matters is the tradeoff between consumption and mortality risk to the individual who is affected. Schelling (1968) argued this point persuasively at a Brookings conference more than 40 years ago. The value to the individual influences behavior and should be the starting value for public decisions which affect risks to the individual's life. This point is a reminder that gross national product, or national income measured with traditional accounting, is a highly imperfect indicator of well being.

Costs of Illness

In valuing investments in health, Mushkin (1962) added to earnings the saving of future health expenditures. The sum of these health expenditures saved (direct costs) and the labor earnings not forgone (indirect costs) became known as the 'cost of illness' avoided. Cost of illness was used extensively because of the wide acceptance of the importance of investment in human beings and because estimation was manageable. The shortcoming that homemakers would be valued at zero was overcome by estimating the value of the services performed or the amount of earnings the person would have had if the individual had worked in the labor market. Low values for infants whose future earnings were heavily discounted and zero values for retirees who are not in the market remain awkward implications. The most troublesome aspect of cost of illness, however, is the lack of a theoretical basis which should include the individual's own value of living. Tolley et al. (1994) provide a comparison of the cost of illness and the value of life based on an individual's willingness to trade money and risk.

Ex Ante and Unidentifiable

Equation [2] displays another characteristic which is inherent in the relevant situations. The value of a statistical life with one fewer person of 10 000 people dying and the value of reduction in mortality risk by 0.0001 share an *ex ante* perspective. The situation is confronted, the life lottery must be played, but the outcome is not yet known. The identity of the individual who would have been the ninth death among the 10 000 is not known. Alternatively, whether the individual facing a lower probability of death survives or dies is not known. Decisions which must be made by individuals and societies about risks to their health, safety, and environment are often made in a similar manner.

Situations in which the individual is identifiable are inherently different. If the individual is thrust into a life-threatening situation by an unforeseen natural event, such as a tornado which causes entrapment in a collapsed building, the individual and society will often spend whatever is available or do whatever is possible to save the life. The situation involves a potentially large change in survival for a known individual whose probability of survival has fallen greatly. Saving the individual's life from almost certain death is usually valued highly. If the trapped person is saved, all may end well. If the person cannot be found in the collapsed building after some time, then the probability of saving the person becomes small and the rescue effort decision is transformed into one involving the more typical value of a change in mortality risk. Medical situations involving identifiable patients with known diagnoses have some similarities.

Court cases involving wrongful death of a specific individual are also inherently different because they too are *ex post*. Nothing can change the fact that the individual is dead. Nothing can be done to compensate the deceased for death. The value relevant to forensic decisions is the amount that can compensate the estate for the individual's death. The value depends on the deceased individual's contribution to the well being of the other members of the family, an amount that is related to labor market earnings. From an efficiency

perspective, the value relevant for forensic situations should consider generating sufficient incentive to influence future decision makers who deal with similar risks. Viscusi (2007) compares the different concepts used in public policy and in court cases.

Criticisms of Value of Life

A value of life based on individual preferences as defined above is not without criticism. Criticism ranges from the ethical to the technical.

Deontology

One saying goes that economists know the price of everything and the value of nothing. In this spirit, one objection to the value of life as defined above is that it is vulgar and ethically wrong to place a monetary value on human life. Deontologists such as Plato or Kant espouse moral theory based on obligate moral rules independent of the desirability of the consequences of acting on the rules. If it is morally wrong that people are exposed to risks of death, then it is wrong to construct a value of life to be used to guide decisions involving risks of death.

In contrast, teleologists such as Bentham or Mill whose moral theory is based on the goodness of the consequences are highly interested in a value of life which might guide decisions so as to generate the greatest good for the greatest number. Teleology is the ethical basis for benefit cost analysis including analyses that use values of life (values of small changes in risk) in evaluating policy alternatives. Absolutist deontology can play a useful role in ruling out objectionable policies which many deem morally wrong. However, categorical criticism of applying individuals' values of changes in their own risks in analysis tends to reduce transparency by driving unavoidable tradeoffs from consideration rather than explicitly including them in the analysis. See Brandt-Rauf and Brandt-Rauf (1980), who analyze the ethical conflict over occupational safety and health.

Tension and misunderstanding associated with the value of life concept might well be reduced with terminology that emphasizes small tradeoffs for risks instead of dollars for life. Cameron (2010) makes the case that a term such as microrisk that describes the willingness to swap the value of alternative goods and services for small changes in risks would be a cosmetic change well worth making. Such change is probably unnecessary in countries that accept benefit cost analysis as routine. However, careful wording might calm policy discussion in others, such as the US, and avoid deontological mischaracterizations of changes as devaluation of life, see Viscusi (2009).

No Single Value

Equation [2] is useful for demonstrating that there is no single value of life which applies to all individuals in all circumstances. The amount an individual is willing to trade for a small change in his or her probability of survival depends on P, the base level of the probability. Because P is in the denominator, the value of life can be expected to increase as P decreases. For example, adult aging reduces the probability of survival and can be expected to increase the value of life, holding constant consumption. Automobile drivers who must travel alone at night on winding roads covered with snow and ice (facing lower P) can be expected to have higher values of life than at other times.

The value of life depends on idiosyncratic factors that are reflected in the utility function. $U(C)$ can vary among individuals with the same measured consumption, C, owing to differences in family, environment, or genes. Individuals enjoying close, supportive family relationships and living in clean, ecologically rich natural environments and societies with high-quality civil institutions and public services can be expected to have higher values of life.

Lastly, from eqn [2] the value of life depends upon C. Since C can be expected to increase with income, $U(C)$, and the value of life will be higher with higher income and consumption. Adult aging can be expected to reduce future consumption and, in turn, value of life. The negative effect of aging due to less future consumption (C) with a shorter time horizon and the positive effect due to lower probability of survival (P) make the net effect of aging on value of life theoretically ambiguous and something to be determined empirically. Given the various factors that determine tradeoffs for risks, there is no reason to expect to find a single value even with this simple model. More complex models consider the value of changes in expected health profiles over remaining life where profiles describe the timing, sizes, and sources of mortality risks change, types of morbidity, and recovery. In such models, there are additional reasons to expect differences in values changes in mortality risks, see Cameron and DeShazo (2012).

Quality-Adjusted Life Years

Early evaluation of medical outcomes was in terms of life years added. Desire to recognize quality of life and deontological objection to money values lead to adjusting a life year added by a quality weight to yield a quality-adjusted life year (QALY). The quality weight for a health state associated with an illness (or injury) can be determined by a direct questioning method. The questioning may be as straightforward as picking a point representing the health state on a straight-line scale between death and full health. It might be deciding what probability of full health in a standard gamble with full health and death as the possible outcomes is equivalent to the health state. QALYs place a value on the expected number of years of life.

QALYs emerged to be used in cost utility, or cost effectiveness in evaluating medical interventions for several reasons. One reason was the deontological repugnance for health professionals of putting a monetary value on changes in health and, especially, life. Another was the relative paucity and suspected unreliability of estimates of individual willingness to pay in the 1980s when QALYs were being developed. Given the current abundance of good information about willingness to pay for changes in mortality risks and the tenuous theoretical grounding for QALYs, use of QALYs for benefit–cost analysis involving mortality risks is questionable. For morbidity risks (nonfatal illness or injury) the continued refinement of contingent valuation and the sizable stock of QALY estimates suggest future practice is likely to blend willingness to pay,

QALYs, and related measures such as disability-adjusted life years (DALYs). See Gold et al. (1996), Johannesson (1996), Drummond et al. (1997), and Kenkel (2006). All are consequentialist in that they focus on the values of outcomes.

Estimates of Value of Life

Value of life is about private choices that individuals make implicitly and explicitly about their own health and safety. Bland, healthy diets are traded for tasty food and drink which increase blood pressure and cholesterol levels. Comfortable, safe dwellings are left for skiing and rock climbing. Jaywalking is done to save valuable time. Time and sweat are spent exercising to improve physical condition. Travel is modified to cope with treacherous conditions and increase the chances of a safe trip. Jobs are given up to pursue a safer, healthier lifestyle. For such tradeoffs, if the changes in risk and the values of whatever is traded are known by the individuals and can be known by researchers, then values of life can be estimated by analysis of observable behavior. Even with the insights and complexities that behavioral economics adds, these values can be useful for policy analysis, see Robinson and Hammitt (2011).

In addition, if realistic risk tradeoff scenarios can be constructed, then values of life can be elicited directly. Values of life have been estimated using these approaches at least since the early 1970s. The models upon which the estimation is based typically use a utility function which in some way resembles the one shown in eqn [1], make P endogenous so that individuals can change the probability of survival through their behavior, and finally introduce a resource constraint to reflect limited money and time. An implication of these models is that individuals will engage in risk-changing activity to the extent that the marginal value of the activity equals the marginal cost. Letting V be the value of life as defined in eqn [2], P' the change in the probability of survival, and K the cost of changing P, the condition of interest is

$$VP' = K \qquad [3]$$

If P', the change in risk, and K, the cost of changing P, can be determined, then V, the value of life implied by individual behavior, can be estimated. See Cropper and Freeman (1991), Freeman (2003), Johansson (1995), and Johannesson (1996).

Risk-Compensating Wages

The labor market has proven to be a fertile area for producing estimates of individuals' willingness to trade off safety and money. Faced with an array of jobs with different characteristics, workers will choose jobs that suit them best. If two identical workers are confronted with two jobs which are known to be identical except for risk of death associated with the job and pay, then equilibrium implies that the worker who chooses the riskier job must be compensated by a higher wage. This risk-compensating wage difference implies a value of life.

For example, if the estimated tradeoff is \$0.25 per hour in wage for an additional 0.0001 in annual mortality risk and the individual works 2000 h per year, the wage premium is \$500 per year. Multiplying by 10 000 to standardize to a unit risk change (for convenience) means the implied value of life is \$5 million.

Metaanalyses of the many wage-risk studies done for the US and countries around the world yield a range of estimates from \$2 million to \$12 million with an average nearer to the upper end, perhaps \$7 million. (These values are reported in 2011 US dollars as are all estimates reported below. Adjustments are made for inflation using the Consumer Price Index, but none is made for changes in real income over time.) Several concerns exist about the reliability of these estimates. The fatality rates used to measure risk may not reflect actual risks on the job. Worker information about the risks may be lacking or worker perception of the risks may not reflect actual risks. Risks of nonfatal injury risks may be correlated with fatality risks and may not be measured well or at all. Unmeasured and omitted job disamenities may be correlated with fatality risks. Estimates of values of life may not be representative because of self-selection. Recent studies that use risk data that more clearly match workers' jobs and panel data that control for unobserved worker risk ability and productivity characteristics address a number of these concerns. For a review of the *metaanalyses* and advances made in recent studies, see Cropper et al. (2011).

Risk Tradeoffs in Consumption

Markets other than the labor market and activities other than work have also produced estimates of individuals' willingness to trade off safety and other things they value. By estimating the effect of environmental quality on housing values and isolating the effect of environmental quality on mortality risks, the value of life implicit in the housing market can be estimated. By estimating the effect of the occupant fatality rate on the prices of automobiles, the value of life implicit in the automobile market can be estimated. These situations match well with eqn [3] in that numerous options are available from which the consumer can choose. Other consumption decisions are less continuous, but still imply values of life. Wearing a seat belt while driving in a motor vehicle involves a tradeoff between the gain in safety versus the time and discomfort associated with belt use. Installing smoke detectors involves a tradeoff between a reduction in risk of a fatal fire and installation costs. Blomquist's (2004) review suggests that value of life estimates from consumption studies tend to be less than the estimates from the labor market and fall in the range of \$2 million to \$9 million with a best estimate around \$5 million.

The concerns about the reliability of these estimates are similar to the estimates from the labor market. Some concerns can be readily addressed. For example, if risks are misperceived according to known relationships, the implied values of life can be adjusted. Two other concerns may not be addressed as easily. One is about the ability to separate the risk of fatality from other characteristics of the product. The other is the ability to estimate the value of disutility associated with the consumption.

Stated Preferences in Contingent Markets

Early in the emergence of value of life based on individual willingness to pay, Schelling (1968: pp. 143–144) and Mishan

(1971: p. 174) encouraged economists to employ a questionnaire method to estimate values of life. Since the early 1970s, economists working primarily in environmental, safety, and health economics have developed the stated preference methods. These methods elicit tradeoff choices through direct questioning of individuals who state their preferences about the situation confronting them. The hypothetical setting or market is described, the choice is presented, and information about the respondent is collected. The survey might be in person, by mail, by phone, or some combination. Individuals have been presented with more rapid-response ambulance service for higher taxes, changes in risk on the job for compensating changes in wages, safer highway travel for more money, and safer medications for more out-of-pocket expense. Risk–dollar, risk–risk, and hybrid risk–risk and risk–dollar tradeoffs have been designed to elicit values of life. Contingent valuation, choice experiments, and other stated preference methods have been used in laboratory and field settings for valuing changes in mortality risks due to pollution, travel, and medical treatment. *Metaanalyses* of the many stated preference estimates tend to fall in the range of $2 million to $8 million, somewhat less than the estimates from the labor market and closer to the estimates from tradeoffs in consumption.

A great advantage of contingent valuation is the ability to provide information and describe the tradeoff precisely. Concern exists about reliability. One is related to the challenge of successfully communicating small changes in risk. Another more worrisome concern is potential hypothetical bias due to not actually having to pay. Skepticism remains, but substantial progress has been made through internal validity checks and innovations such as cheap talk pleas for individuals to say what they would really do, convincing individuals that their responses matter and are consequential for policy, and adjusting responses by how certain they are. Future research should increase confidence in these estimates. For a review of the *metaanalyses* and issues, see Cropper et al. (2011).

Heterogeneity

Values for Various Types of Individuals

Benefit–cost analysis of environmental, health, and safety proposals value anticipated changes in mortality risks using the average of values of life for all members of society. In this way the values which individuals place on their own lives inform public policy. For public policies such as improvements in traffic safety which have broad effects across many types of individuals in society, average values of life are appropriate. However, some policies primarily affect specific types of individuals who may have values of life which differ from the typical individual. Whether it is socially acceptable to value changes in mortality risks differently is a sensitive issue. Using different values for differences in gender, race, and lifestyle is usually not considered. A consensus seems to be emerging in the US that it is unacceptable to use different values for groups which differ by income; an average value of life across all of society is normally used. However, adjustments to average values based on income changes over time and across countries are made. Robinson (2007) discusses income and age adjustments in the USA. While no consensus exists yet concerning what is politically acceptable regarding age, research has been done estimating values of life for individuals of different ages. An entire issue of the *Journal of Risk and Uncertainty* (Viscusi, 2010) is devoted to heterogeneity of the value of statistical life with respect to factors such as income and responsibility as well as age.

Values for Children, Working-Age Adults, and Seniors

Values for seniors (age over 65) and children (age under 18) are of special interest because they are vulnerable groups. Life-cycle models of value of life often imply that value of life will vary with age, in part, because of discounting. Discounting future risks can be relevant to people of all ages, but it can matter greatly for the very young, for whom the distant future is discounted greatly. For senior adults there are fewer future periods. A possible offsetting factor for seniors is that they often have accumulated more economic resources. Early contingent valuation studies in the USA and Sweden which address age and discounting find lower values of life for the elderly and that future changes in mortality risks are discounted substantially. See Cropper et al. (1994) and Johannesson et al. (1997). For adults, the issue evolved into a question about discounting the value of life years (VSLYs) and whether VSLY remains constant over the life cycle, see Hammitt (2007).

The vast literature on wage-risk tradeoffs provides estimates of how values of life vary with age for workers. The most recent labor market studies use age-specific fatality rates, estimate by age cohorts, and account for life cycle consumption patterns. The review by Aldy and Viscusi (2007) finds that VSL increases with age peaks at midworklife and declines with the decline flatter than the increase. Stated preference studies have the advantage of including individuals of all ages and those not working in the labor market. Characterizing the effect of age depends on how quality is judged and how much weight is put on different studies, but the review by Krupnick (2007) finds the value of mortality risks appears to be fairly constant during adult life until declining moderately for seniors. The labor market studies point to a value of mortality risks for seniors that is less than the value for midcareer workers, and the stated preference studies give a hint that seniors older than 70 have a value that is only slightly less. A notable recent study by Cameron and DeShazo (2012) that estimates values of mortality risk reductions implicit in values of changes in complex life health profiles finds that values for age 75 are less than half of values for age 65. Currently, no senior discount is made in the US or Europe.

The literature for valuation of mortality risks for children is not as developed as it is for adults, but there has been recent activity. US EPA (2003) developed a special handbook on valuation of children's health risks, but did not suggest different values due to the paucity of estimates. Early estimates based on parents' provision of travel safety for their children hinted at values that were at least equal to parents' value of their own mortality (and morbidity) risks and probably greater, see Blomquist (2004). The Organization for Economic Cooperation and Development (OECD) devoted an entire book (Scapecchi, 2006) to economic evaluation of health risks to children. In that book Dickie and Gerking (2006) model ways in which distributions of resources within households can

influence parents' values of children's risk. They estimate values of reduction in cancer risks for children and find that values for children are markedly greater than parents' values of changes in their own risks. Two other recent, stated preference studies elicit parents' values of reducing fatal risks from consuming pesticide residue in food and from adverse reactions to asthma medication. Both Hammitt and Haninger (2010) and Blomquist et al. (2011) find parents' values of mortality risk reductions are roughly 80% greater than their values of risk reductions for themselves. A calibrated model of valuation of changes in life expectancy in which parents are altruistic and fertility is endogenous produces a similar result; see Birchenall and Soares (2009). OECD (2012) is now willing to recommend no age adjustment for adults, but values of life for children that are 1.5–2.0 times the average adult value. In the US valuing reductions in mortality risks for children more than for adults for policy might be better received than the senior discount. More research on value heterogeneity with respect to age will be valuable. For example, parents values of children's health risks may well depend on resource allocation in the household, characteristics of the parent or child, or opportunities for reducing health risks for each child. Much is known about values for typical adults, but much less about values for the very young and very old.

Values of Others' Lives – Altruism

Values which individuals place on changes in their own probabilities of survival may be less than the value to all of society because the values that others place on the individual's life are not counted. The strongest case for including others' values is within the individual's immediate family. Since people sort themselves into households based on mutual caring it makes sense that interdependencies are greatest within the household. Bonds within the household are thought to be strong enough that decision making is sometimes modeled at the household level and transfers are made within the household. Models of parents' values of children's risks are based on altruism within the household. Beyond the household it is not clear that the values others have for an individual's change in the probability of survival should be included in benefit–cost analysis. In a general model of a society constrained by limited resources, it can be demonstrated that the value of a statistical life is the same with universal pure altruism with caring about the overall well being of others and universal pure self-interest with no caring at all for others. In other words, the individual's value of his or her change in risk need not be supplemented for benefit–cost analysis. This result follows from the recognition that adding others' values causes the individual to consume more health and safety and less of other desirable things than the individual would choose to consume. The individual's value is sufficient as long as there is no substantial concern with the distribution of income. With impure, safety-focused, paternalistic altruism, however, it can be appropriate to augment the individual's value by others' willingness to pay. How much, if at all, altruism outside the household should augment individuals' values of their own mortality risk is a fascinating question that remains a topic for future research. For further readings, see Jones-Lee (1992), Johansson (1995), and Bergstrom (2006).

Public Expenditures and Social Burden

Another reason for considering adjusting the individual value of life is the impact that an individual's death has on others through public tax and expenditure programs. Bailey (1980) argued for the use of individual value of life for guiding policy decisions. One adjustment he made was for the individual's contribution to the public tax and insurance system. The amount of adjustment is potentially greater the more extensive is the welfare state in the society to which the individual belongs. More recently, the observation that lifestyle impacts government expenditures on health has led to something which might be called social burden analysis. The monetary impact on others of individuals who smoke cigarettes, drink heavily, or have sedentary lifestyles has been estimated. Such social burden calculations are not estimates of value of life in that they do not represent values of small changes in mortality risks. They are not individual's values, but are an external effect. Interestingly, if there is a net expenditure burden and it were considered as an adjustment to individual values of life for benefit–cost analysis, adjusted values would be lower than average values of life; benefits of an environmental program would be less than if it affected groups with healthier lifestyles. However, the social burden notion is rarely used this way. Also interesting is the inconsistency with which impacts on government revenues and expenditures are included in the burden analysis. For example, a RAND Corp. study by Manning et al. (1991) estimates that smokers, roughly speaking, pay their own way because of the excise taxes they pay on cigarettes and the amounts they bequeath to survivors through net contributions to pension plans because smokers die younger. Others who do burden analysis, including those who determine what is admissible in court, are more selective in what they are willing to accept as relevant. They will count increases in some medical costs financed by others such as those associated with hospitalization but exclude other medical costs which would be saved, such as costs of long-term care. Social burden analysis awaits a theoretical grounding to put it on equal footing with benefit–cost analysis. Social burden aside, changes in government surplus (revenue-expenditure) can be theoretically appropriate to include along with changes in consumer and producer surpluses in benefit-cost analysis of policies that change mortality risks. Such a benefit–cost analysis would not arbitrarily exclude relevant changes in expenditures and revenues; see Boardman et al. (2011).

What Is Known

What may seem on the surface to be impossible, placing an economic value on life, for practical purposes is straightforward. People, individually and collectively, make choices all the time in which they implicitly make tradeoffs between small changes in their probability of survival and finite amounts of valuable time and money. For more than 40 years economists have recognized these values as conceptually preferred. Estimates of these values of statistical lives, or, alternatively, values of changes in mortality risks, come from analysis of jobs with different wages and risks, consumption decisions involving

changes in risk and time and money, and from direct questioning involving risk-money tradeoffs in constructed markets. The evidence from a large number and wide variety of studies suggests the typical value of life for adults falls in a range from $2 million to $12 million (2011 US dollars) with estimates from consumption and contingent valuation tending to be less than estimates from the labor market. This range may seem wide, but it has proven useful in many policy analyses which often turn on other factors. Theoretically no single value of life is expected. Age is expected to be a relevant characteristic, but possibly in a complex way. Evidence that values are lower for seniors is mixed, but the evidence for children suggests values for young children are 1.5–2.0 times the values for typical adults. Altruism is thought to be the greatest for children in the household where ties are close. The fact that these theoretically preferred, willingness-to-pay values have displaced the early measure, cost-of-illness, matters because they are typically greater although the relationship is not exact. The displacement of QALYs for valuing changes in length of life has allowed moving beyond cost effectiveness analysis among alternative health interventions. Deontological and estimation issues aside, the economic values of life based on tradeoffs for small changes in mortality risks is likely to continue to be useful in policy decisions about health, safety, and the environment.

Value Pluralism

Ruth Chang, Rutgers University, New Brunswick, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Value pluralism' as traditionally understood is the metaphysical thesis that there are many values that cannot be 'reduced' to a single 'supervalue.' While it is widely assumed that value pluralism is true, the case for value pluralism depends on resolution of a neglected question in value theory: How are values properly individuated? Value pluralism has been thought to be important in two main ways. If values are plural, any theory that relies on value monism, for example, hedonistic utilitarianism, is mistaken. The plurality of values is also thought to raise problems for rational choice. If two irreducibly distinct values conflict, it seems that there is no common ground that justifies choosing one over the other. The metaphysical plurality of values does not, however, have the implications for rational choice that many have supposed. A charitable interpretation of value pluralist writings suggests a 'nonreductive' form of value pluralism. Nonreductive value pluralism maintains that in the context of practical choice, there are differences between values – whether or not those values reduce to a single supervalue – that have important implications for rational choice. This article examines the main arguments for metaphysical value pluralism, argues that metaphysical value pluralism does not have certain implications that it is widely thought to have, and outlines three forms of nonreductive value pluralism.

'Value pluralism' as traditionally understood is the metaphysical thesis that there are many values that cannot be 'reduced' to a single 'supervalue.' Although value monism has an impressive pedigree of proponents (e.g., Bentham, Mill, and, arguably, Aristotle and Nietzsche among others), it is now widely assumed to be false. The arguments for value pluralism, however, are surprisingly inconclusive. Indeed, as we will see, they critically depend on the resolution of a neglected question in value theory: How are values properly individuated?

The metaphysical plurality of values has been thought to be important in two main ways. First, if values are plural, any theory that relies on value monism is mistaken. So, for example, hedonistic utilitarianism and most forms of preference-utilitarianism must be rejected. Second, the plurality of values is thought to raise problems for rational choice. If justice, for instance, is irreducibly distinct from mercy, how can there be rational choice between them? Without reduction, it seems there is no common ground that justifies choosing one value over another.

On closer inspection, however, it turns out that metaphysical or reductive value pluralism does not have the implications for rational choice that many have supposed. A charitable interpretation of value pluralist writings suggests a second, nonreductive, form of value pluralism. Nonreductive pluralism is neutral on the metaphysical question of plurality but insists that in the context of choice, there are differences between values – whether or not those values reduce to a single supervalue – that have important implications for rational choice. Since the differences claimed to hold between values vary from author to author, nonreductive value pluralism is not itself a particular view about values but merely a convenient rubric under which a loose collection of different views about values may be grouped.

This article examines the main arguments for reductive value pluralism, argues that reductive value pluralism does not have certain implications it is widely thought to have, and outlines three forms of nonreductive value pluralism.

Reductive Value Pluralism

Value pluralists maintain that whatever values are, there are ultimately many of them: They do not all reduce to a single ultimate value (Berlin, 1950, 1959; Nagel 1979; Richardson 1994; Taylor 1982). Exactly how this metaphysical thesis is to be understood depends on how the notion of reduction is to be understood.

Reduction in the context of values is best understood as an explanatory relation: If one value reduces to another, what it is to bear the one value is fully explained by what it is to bear, promote, or respect the other value. This reduction is neutral on the general ontological question of whether there 'really' are any values at all. The pluralist maintains only that there are many values, whether or not they are to be regarded as entities in their own right.

Two paradigmatic relations of explanatory reduction are 'is merely instrumental to' and 'is wholly constituted by.' (Others include 'is merely symbolic of,' 'is merely contributory to,' 'is merely a part of'). If one value is merely instrumental to another, there is nothing more to having the one value than promoting the value it is a means to. For example, if beauty is merely instrumental to pleasure, what it is to be beautiful is fully explained by the pleasure it brings. If one value is wholly constituted by another, there is nothing more to having the one value than being a way in which the other value is borne. For example, if the evening's pleasure is wholly constituted by the thrill at the gaming tables, what it is to have the evening's pleasure is fully explained by the thrill it is constituted by.

If all values reduce to a single value, that value is the only ultimate value, and value monism is correct. If, however, there is something more to two or more values than the values they are instrumental to, constituted by, etc., then those values are irreducibly distinct, and value pluralism is correct.

Three Arguments for Reductive Value Pluralism

Although there has been no agreement on which is the one value to which all others reduce, the view that there is such a value has

two main attractions. If all values reduce to one, then values can be neatly systematized as instruments to, constituted by, etc., a single supervalue. Value monism appears to ensure a simple and elegant axiology, with a supervalue at the trunk of a structure that branches out to the other values that each derive from the supervalue in some way.

Moreover, if value monism holds, it seems that all conflicts between values are only apparent. For if there is ultimately only one value, then options for choice can be tidily arrayed according to how much of the supervalue they bear, promote, or respect. Any evaluative choice would ultimately be a choice between two amounts of the supervalue. Choosing between values would always be like choosing between two lumps of coal or three. Thus, value monism seems to dissolve the threats to practical rationality posed by tragic choices, moral dilemmas, and 'incommensurable' options.

Despite these attractions, most contemporary value theorists assume that value pluralism is true. There are three main arguments for pluralism. First is the intuitive implausibility of value monism: Given the apparent diversity of values, how could there be a single value 'common to' all valuable items? Second is the thought that *akrasia* (actions against one's better judgment) can be explained only if values are plural: How can it make sense for someone to choose something that she believes is worse overall unless there is something attractive about the worse option that is not 'included' in the better one? A closely related third argument maintains that some choice situations involve unavoidable loss: No matter which alternative one chooses, something valuable will be forgone, and thus, there must be plural values at stake in the choice.

Ordinary Intuition

Value monism seems to run afoul of common sense. Two intuitions suggest that any monistic account will be vulnerable to counterexample. First, how could there be just one value that runs through valuable items as diverse as, for example, achieving philosophical insight and eating a slice of delicious cheesecake? While perhaps the value of both options is instrumental to or constituted by some value (e.g., pleasure), it is hard to believe that bearing, promoting, or respecting that value is ultimately all there is to their being valuable. Second, if there were a single value that exhausted the value of all valuable things, the evaluative difference between things could always be given by some *amount* of the supervalue. But how could the difference in value between achieving philosophical insight and eating delicious cheesecake be a matter of quantity of some one thing? It is incredible to think that evaluative differences among diverse goods are just a matter of more or less of a single value.

To these charges, monists offer two replies. The first is to suggest that the troublesome intuitions rely on an uncharitable view of monism, one according to which what it is to bear the supervalue is to bear or bring about a kind of feeling or experience like pleasure or happiness. It is, indeed, hard to believe that all valuable things involve having or producing a pleasurable or happy experience. But monism need not be so crude. Some monists propose instead that the ultimate value is given by the satisfaction of one's 'fully informed' or 'rational' desires or preferences. The one property that runs through all valuable items, then, is the property of satisfying constrained desires, and it is the value of that property that is the supervalue. Evaluative differences between items are a matter of the strength or number of desires they satisfy.

Whether desire-satisfaction accounts of the supervalue are plausible depends on what it is for a desire to be fully informed or rational. Full-information is usually understood as having all the relevant facts and being free from logical error. Rational desires might be procedurally rational (passing certain evaluatively neutral tests) or substantively rational (passing certain evaluative tests). Insofar as full-information or rational is a value-neutral constraint, there is no guarantee that such constrained desires or their strengths will track what is intuitively valuable or more valuable: It is perfectly possible that everyone have fully informed or procedurally rational desires to perform evil and malicious deeds, and that the desires for those deeds be stronger than desires for angelic ones. If, in an effort to secure this tracking, one places evaluative constraints on desires, as one might do by insisting that desires be substantively rational, then one must give up monism. For the values that operate as constraints on desires must be distinct from the value they constrain, and so there are ultimately many values, not one.

Monists have a second, more promising, reply. This reply was introduced by Mill in an effort to defend utilitarianism against counterintuitive consequences of Bentham's quantitative hedonism. There are, Mill insisted, not only different *quantities* of pleasure, but different *qualities* of pleasure. The pleasure of philosophical insight is a 'higher' pleasure than the pleasure of eating delicious cheesecake. Thus, while there is ultimately only one value, there are different qualities of it that explain the seeming diversity of values. Moreover, the evaluative differences between valuable items are not simply given by some *amount* of the supervalue; achieving philosophical insight and eating cheesecake may differ in the *quality* of the supervalue they bear or instantiate – one pleasure is 'higher.'

This reply gets to the heart of the dispute between monists and pluralists. The monist insists that the commonsense belief in multiple values is in fact a belief about different qualities or aspects of a single value. Whether this position is plausible depends on how values are to be individuated. What makes two considerations two distinct values as opposed to two qualities or aspects of a single value? Unfortunately, this question has received almost no philosophical attention. Until the question of how values are to be individuated is settled, ordinary intuitions cannot provide good reasons for thinking value pluralism is true.

Akrasia

Some philosophers (Wiggins, 1978; Nussbaum, 1986) have argued that for *akrasia* to be explained as a coherent phenomenon, plural values are required, and since *akrasia* is a coherent phenomenon, it follows that there are plural values. This argument is often presented as establishing the 'incommensurability' of values, but incommensurability is used here, misleadingly, as synonymous with or as entailing plurality.

If one judges that one has most reason to choose one alternative but instead chooses the other, one is weak of will. Suppose one must choose between going to a party and staying home to work. Although one believes that staying home to work has the greater value – and therefore that one has most reason to

stay home – one chooses to go to the party. How can such a choice be explained? If monism is correct, it seems that weakness of will must be an incoherent phenomenon. For suppose that there is a single ultimate value, say, pleasure. It seems, then, that there is nothing about the lesser option that could possibly attract one to it. For everything the lesser option has going for it – a certain amount of pleasure *X* – is included in what the greater option has going for it – *X* plus more pleasure besides. One cannot choose to stay home for a reason, no matter how bad, for there is no reason for choosing the one option that is not already a reason for choosing the other.

The argument, however, does not succeed in establishing value pluralism. For akratic choice can be explained simply by attributing to the akrates a *belief* that there are plural values at stake, there need not actually *be* plural values. One might mistakenly believe that the value of going to the party is irreducibly distinct from the value of staying home and thus be attracted by the allure of the former. One's reason for going to the party, while based on a false belief, could nevertheless be a reason that makes one's weakness of will coherent.

But perhaps for *akrasia* to be coherent in an 'objective' sense, that is, coherent for agents with, inter alia, relevant beliefs that are true, plural values *are* required. This version, however, also fails. One possible difficulty is that what grounds the akrates' attraction to the lesser option may be not the plurality of the values at stake but rather some contingent feature of the circumstances in which the value of the lesser option is instantiated or realized. So, for example, although there might ultimately be only pleasure at stake, the fact that the lesser pleasure of going to the party occurs in a seedy part of town has a special allure for the akrates. There are arguably no plural values here, only circumstances extrinsic to the supervalue whose special appeal to the agent might provide a reason for choosing the lesser option.

A more significant problem is the fact that attraction to the lesser option can be explained by appeal to different qualities or aspects of the supervalue. Take, for example, a choice between two glasses of wine, one laced with pepper and one not (Stocker, 1990). Although one judges that the unadulterated wine will provide the greater pleasure, one is charmed by the particular pleasure of the wine laced with pepper and so chooses the lesser pleasure for the reason given by its particular charm. Similarly, one might choose to go to the party while judging that staying home is better for the reason that the party option provides a particular quality of the supervalue that staying at home lacks.

The success of this reply depends on an account of the individuation of values. Is what attracts about the lesser option a value distinct from the value of the greater option or some distinctive quality of an ultimate supervalue?

Unavoidable Loss

In some choice situations, it seems that no matter which alternative one chooses, something valuable will be lost. If, for example, one must choose between attending a lecture on Kant's ethics and having cheesecake with friends, one is bound to lose out on value no matter which alternative one chooses – and not simply because one cannot have both. If one chooses to attend the lecture, one will forgo the gustatory pleasure of eating cheesecake; if one chooses to go out for cheesecake, one will forgo the philosophical insight one would have gained at the lecture. The fact that any choice in such situations entails value loss shows that the choice involves a conflict between distinct values. Therefore, there are plural values. (Essentially the same argument is sometimes put in terms of the possibility of rational regret over having foregone a lesser good.)

Monism, it seems, must deny that such cases exist. For if monism were true, then choice would always be a matter of choosing more or less of a single value. If one chooses the option with more value, there is no value loss. If one chooses the option with the lesser value, then there is value loss, but it is not unavoidable.

Both the argument from *akrasia* in its 'objective' form and the argument from unavoidable loss rely on the conviction that values are sometimes *incompatible* with one another: Pursuit of (respect for, instantiation of, etc.) one excludes pursuit of (etc.) the other. It is the incompatibility of values that grounds the akrates' attraction to the lesser option and that ensures that no matter which value one chooses, there will be value loss. This incompatibility of values might be conceptual, as Isaiah Berlin believed was true of value concepts like *justice* and *mercy*, or an intrinsic feature of values given the circumstances in which they arise. If values are incompatible, it seems that they cannot be reduced to a common value.

The monist reply here is already familiar from the previous two arguments. Sophisticated monists of the Millian variety might insist that there can be incompatibilities among different *qualities* or aspects of a single value. In cases of unavoidable loss, there need not be more than one ultimate value. The languorous pleasure of basking in the sun might be incompatible with the piquant pleasure of hearing unexpected good news: Having the one pleasure now rules out having the other now, though they are nevertheless instances of a single value, pleasure (cf. Stocker, 1990). Similarly, the qualitative value of achieving philosophical insight may be incompatible with the qualitative value of eating delicious cheesecake. Choosing between the lecture and the cheesecake involves a loss in value no matter how one chooses, but there is only one ultimate value.

All three arguments for value pluralism crucially depend on the answer to the question, how are values properly individuated? The fundamental idea behind the common monist response to pluralist arguments is that there is a *nonultimate* sense of value according to which it can be true that there are distinct values and yet those values cannot be values in the robust sense implied by the claim that there are two distinct *ultimate* values.

Exactly how this is to be worked out remains to be seen. Hurka (1996) has suggested that one pleasure is not a different ultimate value from another pleasure if it does not differ in any of its intrinsic features. In explaining what it is for a feature to be intrinsic to a value, Hurka urges that the location of a value is extrinsic to it. Thus, John's pleasure and Joanna's pleasure are two instances of the same value, pleasure. Stocker (1990), however, has suggested that if pleasure is located in different people, there are different ultimate values: There is the pleasure-for-John and the pleasure-for-Joanna. Stocker (1990, 1997) maintains that if it is rational to care about any difference between two evaluative considerations, it follows that those considerations are

different ultimate values. Thus, there is sharp disagreement about how values are properly individuated.

Monism, if it is to be plausible, must hold that the correct account of value individuation leaves room for a tenable notion of a value quality or aspect that serves to undermine intuitions that values are plural, accounts for weakness of will, and explains away choices that seem to involve unavoidable loss. If there is such a notion, then value monism may yet win the day. But any such victory for monism may be hollow. For if monism is to be cluttered with complex relations among value qualities or aspects, the two chief attractions of monism – in short, the tidiness and simplicity it seemed to offer – fall by the wayside. In the end, then, the debate between value pluralists and value monists may be much ado about nothing.

Implications of Reductive Value Pluralism

Assuming that there are ultimately many values, what, if anything, of interest follows? There are three main implications that are thought to be important.

First, if reductive value pluralism is true, then reductive value monism and any normative theory that relies on it must be rejected. So, for example, Benthamite utilitarianism has to go. Perhaps more significant is the result that preference utilitarianism, or, more generally, desire-satisfaction theories of value must go. (This is not to say that desire-satisfaction theories of what it is for something *to be* a value must be rejected. One might hold that every value must satisfy some or other desire to be a value while denying that all values reduce to the value of desire satisfaction.) Many economists and some philosophers favor desire-satisfaction accounts of value, and their accounts at the very least require modification if value pluralism is true. Economists who model rational choice on satisfaction of preferences, for example, must relinquish any claim that *goodness* is a matter of satisfaction of one's preferences and instead maintain only that the rationality of choice depends on one's preferences conforming to certain axioms (cf. Broome, 1991). Philosophers who think that individual well-being is the only value there is and that what makes one's life go best is satisfaction of one's desires must give up either the claim that well-being is the only value there is or the claim that well-being is simply a matter of desire-satisfaction.

Some have thought that value pluralism shows that any form of utilitarianism is mistaken. But what is essential to utilitarianism is compatible with value pluralism (Sen, 1981). Others have thought that Kantian ethical theory must be monistic, but neo-Kantians have argued that Kantian ethics is compatible with a plurality of fundamental principles (Hill, 1992). Pluralists have urged that value pluralism is the foundation of political liberalism: If values are metaphysically plural, then liberalism is the correct theory of justice (Galston, 2002). But the metaphysical plurality of values is plausibly neutral between liberalism and nonliberalism. The fact that there are ultimately many values does not entail that a state should not compel its citizens to pursue one value over others, nor does monism entail that a state should not protect its citizens' choices to pursue nonultimate values in ways that do not best promote or respect the supervalue. As some political theorists have pointed out, liberalism itself might be understood as monistic about value: The ultimate value is the value of permitting people to pursue different nonultimate values. Whether there is, in the end, some indirect way in which value pluralism supports liberalism remains an open question.

The classical pluralist theory of morality is W.D. Ross's intuitionism, which posited a multitude of plural foundational, self-evident principles of prima facie duty (Ross, 1930). Many contemporary philosophers have followed in his wake, arguing that there are multiple fundamental values (Nagel, 1979; Finnis, 1980; Griffin, 1986).

A second implication of value pluralism is that it allows for indeterminacy in what ought to be done and thus underwrites the legitimacy of normative disagreement. If values in conflict are irreducibly plural, there may be no truth of the matter as to how they are to be weighed against one another. If you disagree with me about what ought to be done, value pluralism allows that we may both be right. This indeterminacy in what ought to be done in turn entails a kind of relativism – not the sort according to which what is right for you is different from what is right for me, but rather a relativism within each individual as to what ought to be done. For each of us, there may be no determinate right answer as to what we ought to do (Wolf, 1992).

Value pluralism has been thought to have a third implication. If value pluralism is correct, then difficulties supposedly follow for rational choice and deliberation (for general discussion, see Railton, 1992). The difficulties alleged are various, but the reason for thinking that none follows from value pluralism is the same. Many have supposed, for example, that alternatives for choice bearing plural values are *incomparable*. How can the option of respecting someone's right to free speech be compared with an option that doubles everyone's pleasure? Insofar as the value of a right to free speech is irreducibly distinct from the value of pleasure, it seems that there is no common basis on which to make a comparison between their bearers. The argument goes, if options for choice bearing plural values are incomparable, rational choice between them is precluded.

There is good reason, however, to think that the plurality of values does not entail the incomparability of options that bear them. Take any two putatively ultimate values such as the value of the right to free speech and the value of pleasure. One can always imagine some option that bears the one value in a notable way that can be compared with another option that bears the other value in a nominal way. So, for instance, an option that involves violating everyone's right to free speech is worse than an option that involves reducing one person's pleasure by a small amount. Given any two putatively irreducibly distinct values, there will always be some comparison between a notable bearer of the one value with a nominal bearer of the other value. The existence of 'nominal-notable' comparisons demonstrates that if alternatives are incomparable, it is not the plurality of values per se that entails their incomparability (Chang, 1997). Assuming that rational choice depends on the comparability of alternatives, the plurality of values, then, does not preclude rational choice in this way.

Although value pluralism does not entail incomparability, perhaps the issue of value pluralism is important because if value monism is true, complete comparability follows. If there is ultimately only one value, evaluative differences between items must always reduce to differences in amount or quality of the

supervalue, and quantities or qualities of the same thing can always be compared. On some views, if alternatives are comparable, the existence of a rational choice is assured. Thus, monism seems to guarantee that there is a rational choice in every choice situation, no matter how intractable the conflict may seem.

The inference from monism to comparability, however, is mistaken. It is not clear that different qualities of a single value can be compared. How can one compare the luxurious, wallowing pleasure of lying in the sun and the intense, sharp pleasure of quenching a fierce thirst? Making the case for comparability is arguably just as hard under the assumption of monism as it is under the assumption of pluralism. Moreover, even assuming that the supervalue does not admit of different qualities, it is a mistake to assume that all *quantities* of a single supervalue are comparable. Pleasure can be greater in amount without the value of that pleasure being thereby greater. The five-course feast that ends with petit fours involves a larger quantity of pleasure than the five-course feast without, for the petit fours add a quantity of pleasure to the pleasure already had. But the additional quantity of pleasure may make the meal less valuable with respect to pleasure – the petit fours induce pleasure 'overkill.' Since a larger quantity of pleasure is not always better with respect to pleasure, it seems possible in principle that different quantities of a single value are incomparable. Assuming that there are such genuine cases of monistic conflict, the issue of value pluralism cuts across the question of whether bearers of value are comparable or incomparable.

Nonreductive Value Pluralism

In general, the question of how many ultimate values there are is irrelevant to the question of how conflicts between them are to be resolved. What matters in conflict resolution is how the values relate to one another in the context of choice, not how they stand to one another metaphysically. As already suggested, a monist might happily allow conflicts between value qualities, while insisting that, as a metaphysical matter, there is ultimately only one value.

Given that reductive value pluralism does not have the implications for practical reason that many value pluralists seem to think it has, it is natural to think that there is some other notion of value pluralism besides the metaphysical one. There is, however, no single specific idea that would account for the concerns of all value pluralists who think the 'plurality of values' has implications for rational choice. At best, the cluster of views can be generally characterized as holding that there is some or other difference among values – something apart from mere metaphysical numerical difference – that has important implications for rational choice. The loose collection of views about the ways in which differences between values can have practical implications might be called nonreductive value pluralism.

Nonreductive value pluralism comes in many different varieties, but there are three leading kinds (for general discussion see Griffin, 1997). First is the view that some values are *incompatible* that they cannot be pursued (instantiated, etc.) together. The incompatibility of values raises the possibility of unavoidable loss of value and, more alarmingly, the specter of moral dilemmas in which the unavoidable loss of value is expressed by a moral requirement.

Second is the view that some values are so different that they – and therefore their bearers – are *incomparable*. Suppose you must choose between a career as a clarinetist and one as a lawyer (Raz, 1986). If the values of those careers are incomparable, and if their incomparability precludes rational choice between them, it seems that whichever career one chooses, the choice cannot be rational. Thus, this kind of nonreductive value pluralism has important implications for practical reasons. It suggests that there is perhaps a wide swath of choices that are beyond the scope of practical reason.

A third view is that some values are so different that their bearers cannot be measured by the same cardinal scale of value (cf. Sunstein, 1994; Anderson, 1993, 1997). Suppose you must choose between guns and butter. Since there is no cardinal scale along which the value of guns and butter can be measured, the alternatives are *incommensurable*. Many pluralists have thought that rational choice between incommensurable options is impossible. But it is clear that the lack of cardinal comparability does not preclude rational choice. One alternative might be better than another though there is no cardinal scale according to which it is better. Lexically superior options, for instance, cannot be measured on the same cardinal scale as the options they are lexically superior to, but they are nevertheless better. Moreover, the failure of precise cardinal comparability need not entail incomparability. Items may be 'imprecisely' comparable (Parfit, 1984; Ms; Griffin, 1986) or 'indeterminately ranked' (Seung and Bonovac, 1992) or 'on a par' (Chang, 2002). Although incommensurable options do not preclude rational choice, the fact that they are incommensurable entails that any justification for choosing one over another cannot appeal to the idea that there is some amount of one that provides the equivalent *measure* of some amount of the other.

Abstract

The present article examines values and their development across cultures. Since values are central to any understanding of the person as well as the society, they are said to represent desirable goals and guiding principles in people's lives. The article also examines some of the social correlates of values. Values of social collectives representing the cultural level shared values are explored. Examining the research related to shared cultural values, the article suggests the need to look at within cultural variations in values, more specifically examining the differences in values among social and cultural groups so as to have a more nuanced understanding of values in different cultural contexts.

Values and Social Life

The proposition that individuals develop in cultures and that culture frames their values is well accepted in the literature. In other words, how we behave, how we perceive our own and others behavior and how we address social issues and take positions in our social, cultural, and political lives are all influenced by our values. Today, the inextricable and complex linkage of values and culture is even more intense as it has been found that at both personal and cultural levels, values have an impact on the social interactions, judgments, and explanations. Any analysis of values will be incomplete without examining both personal and cultural values because both impact an individual's behavior and social relations. Personal values are the broad socially desirable goals and vary in the importance assigned to them from person to person. They have been posited to serve as guiding principles in people's lives. Divergences in different cultures often induce large variations in personal values. For example, some cultures give more importance to certain values while others give importance to some other values. Asian cultures may give more importance to the traditions than the Western cultures. Even among Asians, individuals may give different degrees of importance to traditions. Thus, we see that individuals belonging to a particular culture may share some values and at the same time differ in other values with their fellow beings. In today's scenario, the composite nature of different cultures may perhaps minimize these differences across cultures but at the same time within a culture, differences in values may get accentuated. It is also important to mention here that culture is not a fixed set of well-defined parameters. Asian and Western cultures have large variations, not only in terms of degree of importance or acceptability of different values but also in terms of intrinsic nature of these values. Even different regions, nations, and states within the same cultural context may have variations in values preferences. But despite saying this, we do find some common strands in values across cultures.

As has been discussed above, it is true that both personal and cultural values, influence the perceptions of legitimacy, acceptance, and effectiveness of behaviors of individuals, groups, and institutions as well as the rejection of certain behaviors. We imbibe and inculcate values as we see and meet others, gain knowledge about acceptable and unacceptable social norms and standards, and adapt to customs and practices held important in one's culture. Values have also been seen to have social functions such as to foster development and progress, facilitate cooperation or competition between groups, and create conflicts as well as to promote harmony, happiness, and peace. In order to understand the numerous social functions of values, it is important to understand the role of various social entities who judge or categorize certain behaviors as socially appropriate or inappropriate, disapprove of others, and even justify their own behavior and demands, based on their values. Before we start delving deep into the role of values and their importance across cultures, it is important to understand what exactly values are. Most scholars see values as representing desirable goals that function as principles in the life of individuals, groups, and societies. They are seen to reflect conceptions of what is preferred and considered appropriate in a given social context. Another important feature of values is that all values are organized hierarchically both in the case of an individual, the society, as well as the culture. Some values may be considered as more important by an individual and some other values by other individuals. This variedness is seen both at the societal level and the cultural level. In other words, not only individuals have a unique value hierarchy, but societies and cultures may also have their own unique hierarchy of values. One set of theories concerning values have postulated that by and large, although people differ in terms of their value priorities, the structure of the human value system is universal (e.g., Schwartz, 1992). People may differ in terms of the relative importance they place on a set of universally important value types.

Values of social and cultural groups allow us to understand shared ideas that a particular social and cultural group considers right and desirable, encourage these in their members, and may consider those who do not espouse these values as outsiders. The maintenance of boundaries between persons, groups, and societies is facilitated and shaped by values. Today, when we are all influenced by the forces of globalization and the fast changes taking place both in the societies and in different cultures worldwide, values seem to be the most affected by these changes. This significance of values to individual and social life, however, has been recognized since long by psychologists, sociologists, anthropologists, philosophers, and other social scientists (Rokeach, 1973;

Schwartz, 1992) .Time and again people have been discussing and debating about values, lamenting the decline in values, and reasserting their impact on behavior, emotions, decisions, and social interactions. Kluckhohn (1951), an anthropologist, was one of the earliest scholars to examine the concept of values. His writings paved the way for later work by providing a definition of values "as a conception, explicit or implicit, distinctive of an individual or characteristics of the group, of the desirable which influences the selection from available modes, mean and ends of action" (p. 395).

One of the more comprehensive research on values was conducted by Rokeach (1973) wherein he defines "a value is an enduring belief that specific mode of conduct or end-state of existence" (p. 5). He posited two set of values – terminal values and instrumental values. By terminal values he referred to the desirable, end states of existence. These consist of goals that a person would like to achieve during his/her lifetime. Different groups of people in various cultures may differ in terms of their terminal values. Instrumental values on the other hand are the modes of behavior that are preferred, which are means of achieving the terminal values.

Schwartz (1992) in his widely acknowledged work, proposed that values pertain to the desirable end states or behaviors. Summarizing the main strands that run through various conceptualizations of values, he highlighted the following attributes of values: values are motivational constructs that transcend specific actions and situations and guide the selection or evaluation of actions, policies, people, and events. Schwartz and Sagiv (1995) further clarified the concept in their articulation of values as "transitional goals (terminal or instrumental)" that reflect both individual and collective goals that are guiding principles in a person's life.

Schwartz (1992) proposed 10 types of values that are distinct but recognized by people in most societies. These include the following. Conformity, which emphasizes going along with others. As a result, those actions that are likely to harm others or will not be liked by others are generally not given importance. Tradition focuses on respect and acceptance. A strong commitment to customs and traditions are endorsed. Values espoused by different religions also come under tradition. Benevolence refers to enhancing the welfare of others or being nurturant. Another value called universalism emphasizes understanding, appreciation, tolerance, and protection of people and nature. The value of self-direction considers safety, harmony, and stability of society, of relationships, and of self as imperative. Excitement, novelty, and accepting challenges in life are emphasized by stimulation, which is another important value in the list. Hedonism emphasizes on pleasure and gratification for oneself. Personal success and competence is referred to as achievement, which was considered by Schwartz as another core value. The last two values in the list consist of power, which is understood in terms of social status and prestige, control, or dominance in the society, and security, which stresses the safety and stability of society, relationships, and the self. Schwartz (1992) further added a dimension of congruence and incongruence to this set of values. Certain values like (1) power and achievement, (2) achievement and hedonism, (3) hedonism and stimulation, (4) stimulation and self-direction, (5) self-direction and universalism, (6) universalism and benevolence, (7) tradition and conformity, (8) conformity and security, and (9) security and power were delineated as congruent values as they go together and at times even support each other. The incongruent values are (1) self-direction and stimulation versus conformity, tradition, and security; (2) universalism and benevolence versus achievement and power; (3) hedonism versus conformity and tradition. For Schwartz, the individual actions taken in the process of exploration of these values have both psychological and social consequences for individuals.

Several popular but cognate concepts in psychology need to be examined to further clarify the meaning of the concept of values. Attitude is one such concept that is generally defined as a relatively enduring organization of beliefs, feelings, and behavioral tendencies toward objects, groups, events, and symbols. Attitudes enable us to evaluate people, behaviors, events, issues, or any object. According to Schwartz (2012) "values underlie our attitudes; they are the basis for our evaluations. We evaluate people, behaviors, events, etc. positively if they promote or protect attainment of the goals we value. We evaluate them negatively if they hinder or threaten attainment of these valued goals. Beliefs are ideas about how true it is that things are related in particular ways. Examples of beliefs are 'war never solves problems,' 'Africa is larger than Europe,' and 'psychologists are wise.' Beliefs vary in how certain we are about their truth and their validity. General beliefs that people hold about how the world functions are called social axioms (Leung and Bond, 2004). Unlike values, beliefs refer to the subjective probability that a relationship it true, not to the importance of goals as a guiding principles in life" (p. 16).

Having clarified the concept of values, another issue related to values is their measurement. Measurement of values has been a challenge for researchers and several attempts have been made in the past, starting from Spranger's (1928) '*Types of men*' wherein he identified major human values, namely, theoretical, economic, aesthetic, social, political, and religious. Allport et al. (1931) operationalized Spranger's list of values. Several other attempts have been made to measure values but the most popular ones are Rokeach's (1973) Values Survey, and Schwartz's (1992) Value Scale. Schwartz is credited with developing a survey that can be used to identify a set of values that can differentiate an individual from another or that can also differentiate a society from another. He asked his respondents to rate the extent to which each of 56 values was a guiding principle in his or her life. The values were presented as a single word or a phrase with a brief clarification of what the author meant by each of them.

The Sociocultural Correlates of Values

The social psychological research has delved into variables in the sociocultural context that are potentially important in shaping value preferences. Age, life stage, educational level, occupational status, and gender, are some of the variables that have received considerable research focus. Some of this research is discussed here to illustrate the trends. Studies have reported that there are differences in values due to age.

Schwartz (1992) reported that young people attributed greater importance to openness (stimulation and hedonism) and less importance to conservation (tradition, conformity, and security). It has been found that younger people expressed more individualistic and less collectivistic values. Also, people living in urban settings in comparison to those living in rural settings typically show more individualistic and less collectivistic orientation and view 'openness to change' and 'universalism' as more important. In the case of gender, it has been argued that men would emphasize agentic-instrumental values like power, whereas women emphasize expressive-communal values like benevolence. In general, women have been found to be more collective, interdependent, relational, and allocentric in comparison to men. Differences in values due to different occupational statuses are also seen and have been demonstrated by studies comparing managers and workers. Most of these studies have reported that managers and workers have distinct value systems. Some studies conducted in India have reported that the managers perceive greater differences between themselves and workers. Education has been another variable that has received research attention. Kohn and Schooler (1983) argued that education has the tendency to promote flexibility, openness, and self-direction values. Results related to education and values are somewhat mixed. Few studies have shown that educational experiences promote intellectual openness, flexibility, and breadth of perspective necessary for self-direction. Education has been found to be related to self-direction and stimulation rather than conformity and tradition. However, some other studies have not shown much differences due to educational status. Despite such mixed results, one would like to acknowledge that schools have been known to encourage the dominant social ideals in most cultural contexts, at times even religious ideals and values. Schools are considered the 'institutions of socialization' and certainly have an impact on values. Therefore, a lot of importance is given to value education in schools in almost all cultures.

Development of Values across Cultures: Differences and Similarities in Value Preferences

Since values are tied to sociocultural context and are shaped by the context, it would not be unfair to say that they are socially and culturally constructed and maintained. The study of values and analysis of cultures is closely linked. Culture provides principles to people to sample information in their environment (Triandis and Suh, 2002). Researchers have looked at culture in different ways. Some have explored culture in terms of structures, some have defined its functions, while others have examined the processes. Whatever be the lens through which culture has been seen, all these conceptions have helped in understanding the impact of culture on human interaction. When trying to make sense of others' behavior, their own behavior, or even taking a stand on issues, people from Eastern cultures may focus more on family reactions (like what will my family/community say, or what will be the repercussions of my action on my family, etc.), which can be referred to as elements of the collective self. These cultures emphasize interdependence among individuals more while people in Western cultures may focus more on their personal self as these societies are more individual oriented. Also, Western culture seems to hold clear-cut dichotomies between the self and the other, man and nature. Thus, we see that there are cultural variations in the way people relate and interact with each other and these are shaped by values. Relationality seems to be very important in Asian cultures but not in Western culture. Cultural values reflect what a social collective would think is right and desirable. How relationality works in Asian cultures and under what conditions it does not work needs exploration.

Another question of interest to theorists working on culture is that can a nation be used as a synonym for culture or also do nations have a culture. Rohner (1984) attempted to answer this question. He proposed that the essence of 'culture' lies in the shared way in which individuals interpret what goes on around them. For example, women in rural parts of northern India generally cover their heads before the elderly. If many people think that covering the head by a woman is a sign of respect for elderly, one can say that there is a shared culture of showing respect to elderly by covering the heads. Rohner further distinguishes between a culture and a social system. In case of a social system, an example of which could be a family or even a nation, the emphasis is on the patterns of shared behavior and interactions. A very important question raised by Smith et al., which ought to be addressed by theorists working in this field is – "are culturally shared meanings achieved because there is a system of shared values and beliefs, or is there some set of normative reference points in a culture that leads individuals to interpret what goes on around them in similar ways even though their values and beliefs differ from those around them?" (p. 6). How does an Indian (originally from an Indian village with his baggage of traditional values) now an immigrant in the United States derive shared meanings? Or to rephrase it differently, how Indian traditional values and individualistic American cultural orientation together influence values of Indian immigrants? People may, however, sometimes behave inconsistently with their personal values. One may value certain things in his or her personal life but behave completely different when interacting with others in a specific cultural or even in a specific situational context. Rohan (2000) was of the view that one's attitudes and behaviors interact with the personal and cultural value systems. Recently, Boer and Fischer (2013) provided an interesting framework that specifies the motivational basis of social attitudes concerning fairness, care, purity, in-group, and authority.

Are there cultural differences within nations? And how theorists handle this is a pertinent question as most cross-cultural psychology research makes national comparisons. It is also true that some nations have more cultural diversity than others. As an Indian, I am certainly aware that within my country from north to south and east to west, there are vast cultural differences. Hence my skepticism for any such research claiming to compare Indian values and people's behavior with other nations, as there are variations in values among Indians from different regions, social groups, etc. As Smith et al. (2013) articulated "nations, as well as the ethnic, regional and socio-economic groups that may be present within them, can be defined as cultures to the extent that there is evidence that their

members interpret the events around them in relatively similar ways. We need next to look at the ways in which cross-cultural psychologists can test for such homogeneity of outlook within any particular social system" (p. 7).

Major Cross-Cultural Value Surveys

A seminal work examining values across cultures was undertaken by Hofstede (1980, 2001). He was associated with a worldwide survey of IBM employees in more than 70 nations, which was later published in his book *Culture's Consequences*. He describes the effects of a society's culture on the values of its members, and further how these values relate to the behavior. In his initial work, he identified four major dimensions along which cultural values could be analyzed: individualism–collectivism; uncertainty avoidance; power distance, and masculinity–femininity. Individualism–collectivism refers to the importance attributed to the self or the collective/society. In collectivistic societies, individuals are more embedded in their groups. Individualism gives more importance to personal distinct choices and individual's achievements. Power distance is another dimension identified by Hofstede, which refers to the degree to which people accept power of institutions and practices or whether people endorse more egalitarian values. The dimension of masculinity–femininity considers the importance given to attributes that are considered masculine. In contrast, femininity refers to nurturance, care, and benevolence. Uncertainty avoidance refers to the stability in things happening. Later, Hofstede added a fifth dimension, i.e., long-term orientation. This refers to how much a society values long-standing – as opposed to short-term – traditions and values. Cultures differ in their emphasis on short-term values in social relations to long-term values. In the 2010 edition of *Cultures and Organizations: Software of the Mind*, Hofstede added a sixth dimension also, which he called indulgence versus self-restraint. This refers to the extent to which members in a society attempt to control their desires and impulses. Indulgent societies provide for gratification of basic human desires while restrained societies are more restrictive and try to regulate basic human desires.

Of all the dimensions proposed by Hofstede, over the years the dimension of individualism and collectivism generated a lot of enthusiasm among researchers and resulted in a lot of research. One of the major criticisms of Hofstede's work is that within a nation, differences based on regions, social class, ethnicity, gender, etc. were not addressed. More recently, Minkov and Hofstede (2012) tested whether there was much variation in values between regions within nations, compared to the variation between nations. Their results show that regional differences in values within nations tend to be somewhat less than differences between nations. This result may be attributed to several methodological issues related to the study but this certainly needs to be further explored. It has also been reported that people's values, specifically people's collectivistic values, are target specific. This brings in other factors in the understanding of people's values. The implication of this assumption is that the target of interaction is the determining factor. When the target is close to the person, more collectivistic behaviors will be shown than when the target is not so close. In other words, for our family, friends, and even at times in-group members, we are guided by collectivistic values; however, for others we may be guided by individualistic values.

Schwartz (1992) (whose work has already been discussed) provided an alternative approach to the study of values across cultures. His view was that any comparison of national level values would not be meaningful unless one has understood the structure of values that are held by individuals. When we know the structure of values within the minds of individuals in various cultures, we may also know whether the psychological meaning given to a value is shared or not. He identified seven dimensions that differentiate societies. These include embeddedness, intellectual autonomy, affective autonomy, hierarchy, egalitarianism, mastery, and harmony.

Another significant work in this area that yields nation-level means for values is based on the World Values Survey (Inglehart, 1997). Beginning in Europe in the 1980s today this survey covers more than 80 nations. Inglehart has analyzed the changes in these values over time and has identified well-being versus on survival and preference for secular-rational versus traditional authority as major dimensions affecting people's political preferences. The famous globe project (House et al., 2004) identified the following societal cultural values: uncertainty avoidance, institutional collectivism, in-group collectivism, power distance, gender egalitarianism, assertiveness, and performance orientation from a survey on business managers in 62 nations. In this survey, managers rated their society 'as it is' and 'as it should be' on nine dimensions of national culture. These societal cultural values were found to be related to various organizational variables.

To sum up, these major value surveys show that cultures develop values that are shared by their members. How do cultural values develop? Suppose in a particular culture, people give preference to the needy in resource allocation. This preference may be due to the fact that resources are scarce in that culture and therefore protecting the needy is an important concern and this develops into a value. Values are generally received through cultural means, especially transmission from parents, teachers, and other socializing agents (in today's time media has a major role) to children. Fischer (2012) suggested that at the national level, one may expect the success or failure of different types of social systems to predict which values will go together. The Euro-American culture emphasizes the individualistic, personal, or independent orientation. In contrast, in many African and Asian cultures, the major focus is on collective, social, and interdependent orientation (Smith and Schwartz, 1997). Religion also specifies the desirable values, end states, or behavior. Although the essence of all religions is the same and the values emphasized by major religions are complementary to each other, differences may be seen. Suar (2013) posits "that values propounded by major religions can be broadly put under three categories: (1) self-purifying values (e.g., truthfulness, honesty, compassion, fasting, right speech, avoidance of murder, adultery and stealing), (2) others' welfare- and service-promoting values (e.g., nonviolence, forgiveness, charity, right understanding, refraining from

bearing false witness against neighbors), and (3) faith-inculcating values in a supreme power/God (daily prayer, pilgrimage, right concentration and submission to God). Values such as avoidance of murder, adultery and stealing are self-purifying and in the context of others are welfare-promoting. Essentially, faith in supreme power, self-control, and others' welfare are the mainsprings of values in all religions" (p. 971). Thus, although religion has impact on personal values and values across cultures, it is also true that dominant religious groups in most cultures define value priorities for most in a particular cultural context but less dominant groups have their own priorities. In order to have a harmonious social order, it is important that value priorities of most groups be recognized.

In different nations, which we may consider as different cultural contexts (although one has to understand that there will be several subcultures in a nation), diverse values get precedence over others. In this section, an examination of values in different national (cultural) contexts will be discussed to examine values across cultures. Needless to say, a lot of this work has been done in work contexts but has ramifications for other contexts also. This is just a sample of some studies that have been done and is by no means exhaustive. Studies from non-Western contexts have been sampled and discussed as compared to Western contexts they are less represented. The concept of 'bao' is a traditional Chinese concept but is important for understanding social relations as well as values (Liu, 1999). Six subconcepts of bao have been identified, some having a positive direction (repayment of gratitude, repayment of favor, and good retribution) and some having a negative direction (retaliation, revenge, and evil retribution). The social significance of bao is that it shapes the way people maintain balance in social relationships. Confucious values emphasize repayment of a grievance with rectitude and returning virtue with virtue. Such reciprocity, which is different from the notion of reciprocity in Western culture, governs social relationships in China. In India, several researchers have focused on Indian work values. These studies show that Indians continue to be hierarchical and are relationship oriented, where family plays a major role in people's lives. Relationship orientation, harmony and tolerance, norms and duty, and preference for hierarchy are quite important in the contemporary Indian society. In general, the Indian society has been considered as collectivist. The main features of collectivists include interdependent self-construal, compatibility with in-group goals, roles of norms, duties, and obligations in determining social behaviors, and priority to relationships. People try to remain embedded in the group. However, as D. Sinha and Tripathi have noted, India is a case of coexistence of opposites where both individualistic and collectivistic tendencies are present.

The relationship between values and social identity has been a concern for many researchers in different parts of the world, particularly in the region considered to be high on individualism. For instance, some studies conducted in Australia have observed that there was close association between endorsing value types of achievement, hedonism, security, and stimulation as associated with assuming Australian identity. In a study conducted in South Africa, it was seen that in case of Afrikaners international harmony and equality were best predicted by being progressive and religious. National strength and order were predicted by being an African speaker for white Afrikaners, while among black South Africans the best predictor was being South African, a global citizen, and progressive. These studies have started looking at the finer variations in values within groups in the same cultural context. This trend needs to continue to facilitate a more in-depth understanding of the development of values across cultures. A multilevel analysis of values examining how individual values interact with values embraced and shared by groups in a specific culture and how such interaction helps to explain values across different cultures needs to be done. Issues regarding stability and change of values in the wake of fast paced changes in most cultures seem to be an important future direction of research.

Abstract

From the anthropological view, values are considered important sociocultural indicators, deriving from and diversified by human thought and interaction. Values are an inextricable part of the anthropologist's work and are commonly identified as points of interest in contemporary topics spanning a variety of disciplines. As part and parcel of the human experience, the worth of value studies continues to be emphasized.

Contemporary anthropology views values through a holistic lens, acknowledging both their diversity and their subjectivity. Values are seen as both interconnected and varied within and between individuals and contexts of culture, space, and time. Anthropologically, values are seen as human (i.e., psychosocial–cultural) constructions, yet, once constructed, values define the good and the bad, and hence guide and even control behavior. As a discipline centered on the investigation of humans and their constructions, anthropology is appropriately situated to analyze values, their implications, and their importance (Peacock, 1986).

The importance of values in anthropology was recognized by the mid-twentieth century by the designation of two chapters on this topic in Alfred Kroeber's *Anthropology Today: An Encyclopedic Inventory* (1952). Both chapters were written by philosophers, F.S.C. Northrop and David Bidney, rather than practicing anthropologists, which perhaps suggests a sense that the topic should be grounded in a humanistic tradition. Both authors trace philosophical underpinnings while also discussing issues still current such as the debate between cultural relativism and human rights. While this article is much briefer than the two noted, they serve as a baseline against which we can note new developments.

Clyde Kluckhohn, a foremost influential author of one anthropological theory of value, notes that values, in the sense of 'conceptions of the desirable,' tend to be justified morally by aesthetic judgment, reasoning, or some combination of these (Kluckhohn, 1951). Religious practice is one sphere where we find examples of Kluckhohn's morally justified conceptions of the desirable. Religious doctrine and spiritually inspired stories set forth basic principles for living – the belief that one should treat others as one would like to be treated, or the 'golden rule,' exemplifies an *in vivo* ethic. Institutions and individuals alike interpret and disseminate such an ethic, but it is subjects who morally justify, consume, adapt, and integrate this rule for living as a part of their personhood, and it thereby becomes their value.

Values enter anthropology both as a subject for study and as an aspect of the anthropologist's own experience. As a subject for study, values are critical, contemporary topics for investigation in a variety of anthropological subfields. Ecological anthropology, for instance, considers how values affect the way humans interact with and conceptualize their environment and perhaps destroy it. Elucidated by the Society for Applied Anthropology (SfAA), business anthropology considers how ethics are employed in the workplace and studies consumer behavior as it is affected by shared values. In an assessment of 'sense of place' values in Alaska, Brown et al. (2002) further reflect the nuances of the term, indicating that people have and share 'values' and also express 'value' for things – the complex study of valuing economic value is one focus of economic anthropology.

Treating values as an object of study, anthropologists have taken either a cultural or a sociological approach, either emphasizing the patterning of values in themselves and the power of values as cultural conceptions that shape experience, or, *mutatis mutandis*, emphasizing the interrelationship between values and the sociological context.

Examples of the first approach come largely from cultural anthropology in the American tradition (which has philosophical roots in German idealism). Early examples are based on configurationalism: that is, holistic analysis of values that define broad themes of a particular culture. *Patterns of Culture* is the classic example where Ruth Benedict (1934) distinguishes Apollonian and Dionysian values among Plains compared with Pueblo Indians. Later, during and following World War II, Benedict, Mead, and others applied the same approach to whole nations, depicting the dominant values and psychological patterns of Japan, Germany, and Russia; thus was created the national-character school in anthropology (Benedict, 1946; Mead, 1943). Kluckhohn, Vogt, and Albert (1966), and Kluckhohn and Strodbeck (Kluckhohn, 1951; Kluckhohn and Strodbeck, 1961), later refined the somewhat undisciplined holism of these studies by explicitly centering on values. They defined dimensions for comparison and made systematic comparisons of particular ethnic or regional groups within the United States. Clifford Geertz adopted a Parsonian definition of culture (values, symbols, and ideas) that further refined the older configurationalistic notion, and then pursued a Weberian project in his *Religion of Java* (1960), where he distinguished the major divisions within a complex culture according to distinctive values. *Habits of the Heart* (Bellah et al., 1985) applied this approach to the United States, producing an influential critique of American individualism and calling for a return to earlier values that recognized societal responsibility. Early configurationalists along with German influences remained important in these later, Weberian-inspired works; the recurrent theme is that

values, as a manifestation of culture, have meaning and significance irreducible to any societal context.

The second, sociological approach places more importance on social relations, which are viewed as a crucial source and ground of values. Examples of the second approach come classically from the British social anthropological tradition, which had philosophical roots in France, especially in the works of Émile Durkheim. Building from the foundation that thought derives from the relations, experiences, and behaviors we incur as actors in our local social scenes, Durkheim, in *Elementary Forms of Religious Life* (1915), argues that values derive from thought, generally. An excellent application of this thesis is Campbell's *Honor, Family, and Patronage* (1964). Campbell demonstrates cogently how bilateral family patterns explained ideas of honor expressed by the Sarakatsani of Greece. Honor is an ultimate value, for which the Sarakatsani man will sacrifice his life. Yet in this society, honor is rooted in kinship; one's honor depends on one's kin. The values derive from and sustain the family. Campbell's analysis is one of the best in showing the intricate functional integration of value and social organization. Building on this particular analysis, Pitt-Rivers (1983), Peristiany (1992), and others also showed how the concept of honor can be seen as a Middle Eastern and Southern European value, somewhat transcending the uniqueness of social organization but also grounded in a regional cultural and social pattern they termed 'Mediterranean.' Unni Wikan's *In Honor of Fadime* (2008) traces such values to the horrifying case of a young Kurdish woman living in Sweden who was murdered by her father, who felt justified by the dishonor she brought upon her family in having relations with a man outside of her community. In this case, the power of values is explicit: honor is justified by a society, despite undermining basic human rights.

An effort to reduce the first approach to the second was Douglas' *Cultural Bias* (1978). Douglas distinguishes two dimensions of social life, group and grid; the grid is the networks that bind and classify members internally, and the group is the identity of the group contrasted to those outside its boundaries. Utilizing her social variables 'grid' and 'group,' Douglas argues that many cultural values – conceptions of time, of health and disease, and of nature – depend on which particular social configuration is dominant. Thus, by knowing the social pattern, one can predict which cultural value will dominate; the societal configuration explains cultural values.

Since the peak of the cultural and social anthropological structural-functionalist approaches to value, anthropology has developed in a myriad of directions. Comaroff and Comaroff's *Ethnicity, Inc.* (2009) illustrates indigenous groups transmuting their local culture to mimic that of corporations. In the struggle to maintain identity, culture and the values therein are sold as commodities, which are consumed by tourists and companies. Drawing from cases across the globe, the Comaroffs illustrate the globalized, capitalistic forces blurring the distinction between values and value. Further exemplifying the sociological emphasis but with a Marxist twist, one anthropological approach treats political economy as the driving force of culture. This approach tends to diminish the role of values, which are treated as false consciousness, as ideological constructions motivated by class interests, or as a drive to power and profit. Studies of colonialism and postcolonialism illustrate this approach, for example Comaroff's *Body of Power, Spirit of Resistance* (1985), where religious movements and their accompanying values are contextualized within a colonial and postcolonial framework in South Africa.

While anthropologists who emphasize political economy moved values from center stage, the topic has migrated to other disciplines, especially those concerned with globalism and international relations. Huntington's *The Clash of Civilizations* (1996), for example, reifies certain value configurations, notably those of Islam and the West, then foresees the clash between them, replacing the ideological conflict of the Cold War. Scott's *Seeing like a State* (1998) also focuses on the power of values, notably rationalization, when coupled with the state, to shape human life and thought.

Turning to the place of values in anthropology and for the anthropologist, the basic debate is between engagement and objectivity. While Weber's 'value-free social science' concept converges with positivism to express at least an ideal of objectivity, his *Verstehen* converges with a Gadamerian post-modernism to acknowledge the role of values (what Gadamer terms 'prejudice') as projected by the analyst into the process of analysis. These Weberian nuances can still inform the anthropological debate (see, e.g., the debate between D'Andrade and Scheper-Hughes, 1995). Like Weber, anthropologists agree in acknowledging the role of values in their research. Methodologically, this translates as reflexive analysis, the turning of the anthropologist's focus onto him or herself and the values and biases that may influence research or fieldwork. Still, there is debate regarding whether the analyst should attempt to control the influence of values or embrace their influence (i.e., become engaged). Engagement means that the analyst should express rather than suppress values, whether those of one's informants, oneself, or others (e.g., of some ideology or vision of the good). Objectivity means that the analyst should control or suppress the expression of values (other than those of scientific or accurate description and analysis).

A major concern of anthropologists is with the values and ethics governing fieldwork. This concern is illustrated by both history and recent issues treated by the American Anthropological Association (AAA). The overriding principle of the Ethics Code of AAA is "Do no harm to those with whom one does field research." This principle abides in multiple revisions of the code, including the current code (revised in 1998) and pending codes. Means of preventing harm include informed consent (explaining one's research to those involved and insuring that they consent to involvement) and protection against risk, for example by concealing the identity of those involved.

Two examples of controversies expressing this principle are the Darkness at El Dorado affair and the Human Terrain Program (HTP), both of which provoked debate by numerous anthropologists and assessments by committees appointed by AAA. *Darkness in El Dorado* by Patrick Tierney is an expose by a journalist of research by a geneticist, an anthropologist, and others among the Yanomamo of Brazil and Venezuela. The researchers were accused of practices such as taking blood samples inappropriately and manipulating the

Yanomamo inappropriately. Committees appointed by AAA extensively researched these allegations, rejecting some and accepting others. Some claim the controversy threatened the reputations of both individuals and the discipline.

The HTP was instituted by the US military in Afghanistan. Several hundred scholars were recruited to work with the military in combat areas. Such HTP recruits did research on local situations and sometimes established community programs, such as health clinics. A number of anthropologists criticized this effort on the ground that it violated the principle of 'do no harm' in that local people involved in the research or programs could be placed in danger by being brought to the attention of the Taliban. Further, HTP could endanger or jeopardize anthropological fieldwork by allying it with military and intelligence work, hence rebutting claims of objectivity and neutrality. In response to such concerns, an AAA committee has carried out extensive analysis of military practices in relation to anthropology and anthropologists, supporting, to some degree, critiques of the ethics.

Such examples illustrate a general trend for anthropologists and anthropology to link scholarly work and societal issues. One term that captures this trend is 'public anthropology' (Peacock, 1997; Borofsky, 2011). Ronald Niezen's *A World beyond Difference* (Neizen, 2004) offers a searching analysis of a spectrum of values related to practice, with a Human Rights Declaration at one extreme, postulating universal values, and postmodernist refusal to affirm any moral value in terms other than relativistic ones at the other.

In the early twenty-first century, efforts toward defining the place of values in the discipline of anthropology display three major streams. The first affirms positivism and objectivity. The second affirms subjectivity, an interpretive, postmodernist stance leading toward reflexivity – explicit acknowledgment of one's values as part of one's analysis. The third also affirms the place of one's values but leads not so much inward as outward, minimally toward ethical behavior in relation to those among whom one does research, and maximally toward engagement and practice – a mission of reform and change of the world.

The debate about the proper place of values in the experience of the anthropologist is important within the discipline. Arguably of greater impact, however, is the first topic of this article: the anthropological study of value as expressed by humankind. Values will continue to be studied as phenomena deriving from the intricate relations between all worldly things. Anthropology continues to illuminate the importance and worth of these studies, as values are critical elements in the construction and understanding of life by peoples past and present.

Abstract

Values are internalized cognitive structures that guide choices by evoking a sense of basic principles of right and wrong, a sense of priorities, and a willingness to make meaning and see patterns. Like other cognitive constructs, values can be studied at the individual level or at the group level. That is societies, cultures, and other social groups have value-based norms, priorities, and guidelines, which describe what people ought to do if they are to do the 'right,' 'moral,' 'valued' thing. The study of values currently focuses more explicitly on the circumstances in which values predict action.

Values: Psychological Perspectives

Values are internalized cognitive structures that guide choices by evoking a sense of basic principles of right and wrong (e.g., moral values), a sense of priorities (e.g., personal achievement vs group good), and create a willingness to make meaning and see patterns (e.g., trust vs distrust). Like other cognitive constructs, values can be studied at the individual level. However, while it is unusual to discuss attitudes as a group-level phenomenon, values are amenable to analysis at the societal or group level. That is societies, cultures, and other social groups have value-based norms, priorities, and guidelines, which describe what people ought to do if they are to do the 'right,' 'moral,' 'valued' thing. A society, political party, or region can be described as having conservative or liberal values, traditional or progressive values, religious or secular values, and so on.

Values are supposed to influence behavior and people are suspicious of others if they suspect that they hold different values in part because of the presumed link between values and behavior. Knowing a person's value system provides a sense that one also knows what he or she will do in a particular situation or across situations. In spite of the strong belief that values predict behavior, the effect of values on behavior is subject to situational constraints and affordances. That is, if mobilized or made salient, individual values are linked with behavior and choices but not necessarily otherwise.

However, if values do not come to mind, they are unlikely to influence judgment and behavior. Cultures may be said to provide concrete and social embodiments of values. Thus, if cultural values are mobilized or made salient, they also predict behavior and choices of groups and to some extent, of individuals within these groups. Whether cultural cues (e.g., the national flag) serve to cue relevant values may depend on whether their appearance in context seems unremarkable or an obvious attempt to cue a particular value response. Some kinds of values, those that form the basis of moral judgments, appear to have a more visceral effect on judgment, influencing how people feel about a topic, situation, or choice separately from their cognitive evaluation of the topic, situation, or choice. Thus values can cue affective (feeling) as well as cognitive (thinking) responses. The effect of values on judgments and behavior can be seen whether the value is explicitly part of the decision-making or not. That is, a value can be associated with a choice without the association being made explicit.

Overview

This article addresses the following questions. First, what are values, how do psychologists study values, and how are values distinguishable from related concepts – motives, goals, and attitudes? Second, are values best considered at the individual level as located within individuals, or at the context level, as if located in social structures, or are both levels of analyses needed to understand values? Third, what do values imply for behavior? With regard to the first question, values are often studied by asking people to rate how important certain statements are to them or to people in their group. These methods rely on explicit judgments which may be subject to the same variety of constraints as all self-report measures (including, for example, whether people can make explicit judgments about what they value, and social desirability – the desire to say things that the questioner will approve of). Reliance on self-report makes values difficult to study and persistent questions arise as to whether they are 'real,' that is, whether they actually can be shown to have causal influence on behavior.

In spite of this difficulty, values have intuitive appeal as an explanatory construct. Much of everyday life is cast in terms of values, value judgments, or value preferences. Think of ethics, law, religion, politics, education, art, lifestyle, child rearing, and more. Choices in these domains are often explained in terms of values and the value trade-offs one is willing or unwilling to make. Abstract value judgments are embodied in seeming gut reactions that something is right, moral, or natural verses wrong, immoral, or unnatural. Another way to 'see' values in action is to contrast cultures or subcultures in what seems right, natural, or moral.

Empirically, an emerging literature uses priming techniques to show that values matter when brought to mind, not otherwise and that what a value means depends on the context in which it is considered. Values related to loyalty (e.g., patriotism) and to acceptance of authority (e.g., traditionalism), for example, are associated with more trust in government. This effect occurs only in contexts in which government functions brought to mind are relevant to these (e.g., trusting the government to make the right choices for defense spending)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24030-0

not otherwise (e.g., trusting the government to make the right choices for health care). A similar argument has been made for the role of values in acceptance of social policies, polices that appear to come from one's own political party are preferred in part because in-group loyalty is valued.

Another way in which values are studied is by comparison. Comparisons in choices, behavior, social structures have all been used to infer differences in values. One of the great contributions of cultural and cross-cultural research is the way that it brings Western cultural values into sharp relief by making these values stand out in comparison to alternative frames of core values. These and other differences are also found in comparisons of political parties, social classes, religions, and even professions. Consider American cultural values, Americans are said to value life, liberty, and the pursuit of happiness. But what does 'value' mean? Implicitly or explicitly we evaluate or assign value to everything – regarding things as good or bad, a truth or falsity, a virtue or a vice. How do we know? One important means is through values. Values can be thought of as priorities, internal compasses, or springboards for action – moral imperatives. In this way, values or mores are implicit or explicit guides for action; they are general scripts framing what is sought after and what is to be avoided. Values can be thought of as scaffolded on universal human needs for security, autonomy, and connection, which would imply that since all cultures face similar problems they are likely to overlap in values (though not necessarily in their ranking of the importance of each value). To sustain a group, for example, people have to believe that their place within the group is fairly assigned, that authority is justly applied and not used in a harmful way.

Each of these is a value judgment, while the need for these core values may emerge from an evolutionary basis, the relative importance of each value may emerge from socialization within the family. Thus, saying that Americans value life, liberty, and the pursuit of happiness does not necessarily imply that people from other societies value these things less. Rather it implies that Americans are likely to consider security, autonomy, and connection as needing to fit together in ways that maximize autonomy while not undermining security and connection. Moreover, Americans may differ in the relative weight that they put on these core values depending on their social class, political affiliation, and profession, because each of these provides a particular meaning to what connection, security, and autonomy mean. Connection can focus on loyalty to in-group and security can mean purity and sanctity to differing degrees among different groups. This has been studied both by cultural and cross-cultural psychologists interested in cultures of honor and by psychologists interested in morality both generally and as part of the study of other domains, including religion, politics, and organizational processes.

Definitions

Modern theories of values are grounded in the work of Kohn (class and values), Rokeach (general value systems), Merton (social structure and values), and Kluckhohn (group-level values). For example, Rokeach defines values as shared proscriptive or prescriptive beliefs about ideal modes of behavior and end states (outcomes) – what is worth striving for. Social groups couple these ideals about modes of behavior and outcomes with regulations of allowable ways to attain these outcomes. Thus values can focus on both the outcomes and the procedures or process (behaviors) used to attain the outcomes. Moral foundations theory (Haidt and Joseph) builds on this work focusing on moral principles – values one should live by, and bridges from psychological and sociological accounts to anthropological and evolutionary accounts of morality to understand core values, which they term virtues. Actualizing one's talents, enjoying oneself, leading a purposeful life, caring for the next generation are all examples of operationalization of values into behaviors and outcomes.

Values can be conceptualized on the individual and group level. At the individual level, values are internalized social representations or moral beliefs that people appeal to as the ultimate rationale for their actions. Though individuals in a society are likely to differ in the relative importance assigned to a particular value, values are an internalization of sociocultural goals that provide a means of self-regulation of impulses that would otherwise bring individuals in conflict with the needs of the groups and structures within which they live. Thus, discussion of values is intimately tied with social life. At the group level, values are scripts or cultural ideals held in common by members of a group; the group's 'social mind.' Differences in these cultural ideals, especially those with a moral component, determine and distinguish different social systems. In this sense Weber's Protestant 'ethic' and 'spirit' of capitalism describe value systems.

Values, to which individuals feel they owe an allegiance as members of a particular group or society, are seen as the glue that makes social life possible within groups. Yet, they also set the stage for frictions and lack of consensual harmony in intergroup interactions. Values are thus at the heart of the human enterprise; embedded in social systems, they are what makes social order both possible and resistant to change. Values are not simply individual traits, they are social agreements about what is right, good, to be cherished.

What is common to all value phenomena? At the individual level, values contain cognitive and affective elements and have a selective or directional quality; they are internalized. Preference, judgment, and action are commonly explained in terms of values. Values may be grounded in evolutionary press to prefer people, contexts, and situations which do not spread disease or harm, resulting in values of purity, fairness, caring, loyalty to in-group, and acceptance of authority that are differentially emphasized across time, place, and situation. Individuals take on values as part of socialization into a family, group, and society. Once taken on, values are assumed relatively fixed over time (*see* Values Across Cultures, Development of). Indeed, values that are individually endorsed and highly accessible to the individual do predict that individual's behavior. Conversely, even personally endorsed values would not influence action when they are not made salient to the individual at the time of action. Moreover, in any given situation more than one personally endorsed value may apply, and the behavioral choice appropriate for one value may conflict with the behavioral choice appropriate to another value.

Values are codes or general principles guiding action; they are not the actions themselves nor are specific checklists of what to do and when to do it. Thus, two societies can both value achievement but differ tremendously in their norms as to what to achieve, how to achieve, and when pursuing achievement is appropriate. Values underlie the sanctions for some behavioral choices and the rewards for others. A value system presents what is expected and what is hoped for, what is required and what is forbidden. It is not a report of actual behavior but a system of criteria by which behavior is judged and sanctions applied. Values scaffold likes and dislikes, what feels pleasant and unpleasant, and what is deemed a success or failure. Values and value systems are often evoked as rationales for action; for example, values of freedom and equality were evoked to elicit American support for the Civil Rights movements. Values differ from goals in that values provide a general rationale for more specific goals and motivate attainment of goals through particular methods.

History and Current Developments

Initially viewed with suspicion by Western social scientists as too subjective for scientific study, the concept of values found increasing use beginning with *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 1921). Impetus for the study of cultural values comes from the work of Alfred Kroeber, Clyde Kluckhohn, Talcott Parsons, Charles Morris, Robert Redfield, Ralph Linton, Raymond Firth, A.I. Hallowell, and more currently from Michael Bond, Jonathan Haidt, Geerdt Hofstede, Ronald Inglehart, Milton Rokeach, and Shalom Schwartz.

Kluckhohn and Strodtbeck (1961) proposed that cultural value systems are variations of a set of basic value orientations that flow from answers to five basic questions about being. These are first, what is human nature – evil, neutral, mixed, or good? Second, how do we relate to nature or supernatural – subjugation, harmony, or mastery? Third, what is the nature of time – past, present, or future? Fourth, what is the nature of human activity – being, being-in-becoming, or doing? And fifth, what is the nature of our relationship to others – are we joined vertically, horizontally or are we simply separate individuals? Klukhohn and Strodtbeck also organized a system for comparing values in terms of their level of generalization and function in discourse and conduct, proposing that values fit into a pyramid of ascending generalization. For each society, a few central or focal values were proposed to constitute a mutually interdependent set of what makes for the 'good life.' These include the unquestioned, self-justifying premises of the society's value system and definitions of basic and general value terms; for example, happiness, virtue, beauty, and morality. The basic questions raised by Klukhohn and Strodtbeck continue to be studied, for example, by asking if societies differ in the propensity to accept or value vertical relations in which power differential is clear.

Since American researchers dominated values research, much early work focused on documenting American values. As early as 1944, need for achievement was described as an important or even a defining American value which was in decline (Spates, 1983). The idea that American values are in decline continues to be a hot topic of political debate. Some relevant research focuses on change over time in narcissism, the extent that individuals (over) value themselves, and their own needs and desires compared to others.

Early values studies documented the influence of education, age, type of employment, and socioeconomic status on value preferences of Americans, adding to Weber's thesis of the influence of religion (Protestantism vs Catholicism) on achievement and work values in Europe. Kohn (1977) was responsible for a number of important values surveys documenting that in various European countries and the United States, parents of higher socioeconomic status value self-direction in their children more than parents of lower educational and occupational levels. These findings have been verified cross-nationally in 122 societies. The influence of education on values continues to be hotly debated, the concern being that education carries with it reduced acceptance of traditional values (e.g., submission to authority, obedience). However, within the United States, for example, there is no evidence that political party affiliation or religiosity is causally influenced by obtaining a college degree.

Extending the documentation of American values, Rokeach (1973) validated empirically 36 values related to preferred end states and preferred ways of behaving. Using Rokeach's scale, value differences tied to class, age, race, subculture, and level of differences were documented in many countries. Building on Rokeach, Schwartz (1992) delineates values as ways of articulating universal requirements of human existence – to survive physically, have social interchange, and provide group continuity. For Schwartz, values represent operationalizations of these needs as goals that fit together in meaningful clusters (achievement, self-direction, stimulation, hedonism, universalism, benevolence, tradition, conformity, security, and power). Some clusters are compatible (e.g., stimulation and hedonism) and others compete (e.g., self-direction and conformity).

Using mostly data from teachers and college students in 20 primarily Western countries, Schwartz shows that, with the exception of China, specific values mostly do 'cluster' and 'compete' as expected. Thus, 'honest,' 'forgiving,' and 'helpful' cluster together as 'benevolence,' and 'self-direction,' and 'stimulation' cluster far from 'conformity,' 'tradition,' and 'security.' These data suggest important universality to how values are organized cross-culturally and that societies differ in which clusters of values predominate public life.

More recent analyses, using as its base, all literature published between 1980 and 2000 comparing Americans either with one another or with people from other countries on the extent that they endorse values of individualism and collectivism suggest that Americans are neither the most individualistic nor the least collectivistic of people (Oyserman et al., 2002). There was no difference between America and other English-speaking countries and only relatively small differences between Europe (Western and Central) and America, with Americans being higher in individualism. The majority of available studies (40%) focused on comparisons between East Asians and Americans, making them the most common comparison in the cross-national individualism literature. Combined effect sizes for comparisons with East Asia were moderate in size, as were combined effect sizes for Africa and

the Middle East. Whereas these findings corroborate conventional expectations of cultural theorists, surprisingly the combined effect size for countries in the "other Asia" region including India and Pakistan was small. Moreover, no difference in individualism was found between the United States and South America, with Americans in the United States being less individualistic than Latin Americans in South America in more than half of the country samples tested by Oyserman and her colleagues. With regard to collectivism, Americans were found to value collectivism less than were others from all regions of the world, with the exception of English-speaking countries. Surprisingly, Americans were *lower* in collectivism than Europeans were, befitting the idea of a uniquely American way of being (high individualism and low collectivism) but challenging the notion of a single 'Western' cultural set of values. In addition, effect sizes for Asian regions were similar to those for European regions, with large differences in valuing collectivism only when US and African samples were compared. Almost half of all studies focused on comparisons between East-Asian regions and America but effects were heterogeneous implying that simple between group comparisons would not necessarily yield value differences.

Priming people to consider their cultural values changes the extent that they feel obligated to act to help others rather than do their own thing (for a review, Oyserman and Lee, 2008). Values frameworks have been broadened to include Confucian values such as valuing relationships, valuing the family as the model of relationships, valuing a basic benevolence in engaging with others, and valuing hard work, skill development, and thrift (education, industriousness) (Hofstede and Bond, 1988). Cultural researchers have also shown that changes in societies produce rapid changes in values as well as in which personality and social interaction styles are valued. Emotional expressivity and outgoingness are valued more as societies shift toward individualistic values.

Controversies

Key tensions in the values literature focus on the conditions under which they may influence behavior, and the appropriate level of analyses for seeing values in action. Interest in values as a research focus has ebbed in the past as each paradigm for studying values has been criticized for lack of specificity of findings as due to values as distinct from other constructs, including social norms, attitudes, or situational constraints. Current cultural psychology focuses attention on social structures as the repository of values such as personal freedom, group harmony, personal happiness, and duty or filial piety.

How do we know that values exist? A number of options are available: (1) Individual testimony – people say what values they hold. Yet, self-reports of values are subject to pronounced context effects (*see* Attitudes and Behavior). (2) Behavioral choices – either in naturalistic or laboratory settings, value differences may be imputed from behavior. Yet, behavior is influenced by many variables other than values. At the individual level, values themselves are assumed to link to behaviors via their influence on norms and attitudes, but people may infer their values from their behavior, reversing the causal relationship. (3) Cultural and social structures – expenditure of resources, time, energy, and structuring of the natural environment; cultural products can be seen as concrete residues of value-based choices (see Cross-Cultural Psychology; Cultural Psychology). (4) Social interchange – observation of behavior in situations of conflict, and more generally observation of what is rewarded or punished, praised or vilified provides data for identifying what is socially valued. Here, too, the question of appropriate evidence arises. To what extent is it appropriate to assume that differences in social structures and societies are evidence of value differences? Political and economic influences and simple inertia may set the stage for behaviors, without a causal influence of necessarily values.

Future Directions

Cross-cultural perspectives are currently becoming increasingly central to values discussion. For example Inglehart (1990) documented values and value change in a large multinational study, and thus a large number of two-nation comparison studies has emerged. Another important topic of research is the connection between values of individuals, values of subcultural groups, and values of larger cultural systems and methods for identifying and studying each of these. Perhaps in addition to identifying value vocabularies at each level, it is time to begin to ask whether values appropriately are studied as fixed traits of individuals or as embodied in groups and to what extent values research is synonymous with cultural and cross-cultural research.

Given that any particular behavior importantly is influenced by context effects that make certain information salient at the moment of action, it is not surprising that the effects of individual value endorsements on behavior have a 'sometimes you see it, sometimes you don't' quality about them. But focusing on individual endorsement of values may miss much of the power of value systems to influence everyday life. That is, individuals may not need to personally endorse or have salient particular values in order for their influence to be felt. The most profound influence of values may be through the ways that they influence rules, norms, procedures within a society, and in this way structure the everyday life choices for individuals within a society.

Thus, whereas previous researchers have documented values using survey techniques in which individuals rated the extent to which various values were important to them, future assessment of values may need to consider more indirect approaches such as what services a society provides its members, what behaviors are rewarded or sanctioned and so on.

Abstract

Psychologists view values as an aspect of personality that underlies and motivates attitudes and behavior. We present overviews of Allport's motivational theory and Rokeach's cognitive theory, and elaborate on Schwartz's integration of earlier approaches. Schwartz defines values as transsituational goals, varying in importance, that serve as guiding principles in the life of a person or group. Values form a circular motivational continuum that reflects their conflicts and congruence and may be universal. We discuss the location of values in personality structure and relations of values to behavior.

The contemporary psychology of values grew out of two sources: personality psychology, inspired by philosophy, and social psychology, closely linked to sociology. Allport, author of the first psychological theory of values (Allport and Vernon, 1931), pioneered the former approach, drawing upon Dilthey's philosophy and Spranger's personality typology (*Lebensformen*). Durkheim (1897/1964) and Weber (1905/1964) introduced values into sociological discourse as a tool for explaining social structure and social change.

The psychology of personality treats value preferences as individual differences that permit a holistic description of the human being. Sociological approaches treat values as an aspect of culture and study their influences on the individual. Social and cross-cultural psychologists often combine these approaches. They use individual differences in value preferences to understand attitudes and behavior and cultural differences in value emphases to characterize and compare societies or other collectivities.

Of the many theories that have emerged in the history of the psychology of values, three have had the most influence on empirical research. Allport's theory of values (Allport and Vernon, 1931), which was also intended as a psychology of personality, came first. Later, Rokeach (1973) proposed a theory of values as a central aspect of personality useful for understanding individual and group differences in attitudes and behavior. Most recently, Schwartz presented a theory of value content and structure (1992, 1994) that integrated earlier approaches and facilitated values research in many branches of psychology, including personality, social, political, cross-cultural, developmental, and positive psychology as well as in the related disciplines of education, sociology, law, and economics. Below we briefly describe Allport's and Rokeach's theories and elaborate on the Schwartz theory that is currently predominant in psychology. We do not discuss the Inglehart value theory (e.g., Inglehart and Baker, 2000) that is prominent in political science and sociology, because it is not a psychological theory.

Roots of the Contemporary Psychology of Values

Allport's Theory of Values

In formulating his theory, Allport was inspired by Dilthey's psychological and philosophical writings. Dilthey treated psychology as a branch of the humanities (*Geisteswissenschaft*), whose primary goal was to understand rather than to explain, the latter being the domain of the natural sciences (*Naturwissenschaften*). Spranger (1914) followed Dilthey by proposing a personality typology aimed at a holistic description of human beings that would facilitate understanding. Allport and Vernon (1931) viewed this typology as the best a priori theoretical foundation for developing a list of values and constructing a tool for their measurement. According to Spranger, the following six personality types, each characterized by its most prominent values, account for the diversity of human personality. The personality of each individual is a synthesis of the different types, with one being dominant and the others subordinate.

1. Theoretical: truth, intellect, criticism, and individualism
2. Economic: usefulness, frugality, practicality
3. Aesthetic: harmony, beauty, form
4. Religious: a sense of unity with the world, a quest for unity through spiritual development
5. Social: love, respect, help for people
6. Political: power, control over people (not necessarily in the political sphere)

Allport and Vernon (1931) offered a four-point justification for assigning values a privileged role in the study of personality. First, they asserted that measuring isolated traits, capacities, or other specific constructs yields a misleading understanding of personality because such information provides only fragments but not a holistic view of a person. They averred that personality is not the sum of isolated elements but the overarching structure that determines those elements. Second, they argued that the personality of each person is a unique system, not strictly

comparable with any other, and that this assumption is central to a scientific account of personality. Following from the above was their third point: An appropriate construct for investigating personality must be able both to describe each individual as a coherent system rather than a sum of isolated aspects and to provide a precise account of the variety of human personalities. Finally, Allport and Vernon concluded that the value construct best fulfills the requirements in their third point.

Allport and collaborators (Allport and Vernon, 1931) proposed a value instrument to measure personality based on the Spranger typology, entitled *A Study of Values* (SoV). Together with Lindzey, Allport published a modified version of the SoV 20 years later (Allport et al., 1951).

The concept of value that Allport and colleagues adopted combined two psychological meanings: (1) value as an interest and (2) value as an evaluative attitude. Both the original and modified versions of the SoV questionnaire used the terms *values* and *interests* interchangeably. The interpretation of values as interests facilitated the practical application of the SoV and helped to popularize the theory. Applied psychology soon picked up this psychological adaptation of Spranger's typology and employed it in such fields as vocational guidance, management, and education.

When discussing the theoretical foundations of their questionnaire, Allport and Vernon (1931) also used the terms *evaluative attitudes* (or *forms of valuation*) interchangeably with values. Upon perceiving any object, people engage in the everyday activity of evaluation based on their values. Allport and Vernon proposed that people might make six possible types of evaluations, corresponding to the six personality types defined above. In explaining this conception of values as evaluations, they cited Spranger's example of evaluations of a ring. Depending on their dominant values, people may regard a ring as a glittering object (an aesthetic evaluation), an object made of a certain metal (a theoretical evaluation), an object having a certain market value (an economic evaluation), a symbol of love and loyalty (a social evaluation), a symbol of certain rights and duties (a political evaluation), or an object with some sacred or mystical value (a religious evaluation).

As bases of evaluation, values are likely to influence one's perceptions. This view of values created opportunities for empirically verifying their psychological reality in non-questionnaire surveys. In an early review paper, Allport and Cantril (1933) described the first studies of this type (e.g., effects of values on selective perception of the news). The concept of value proposed by Allport was used in the New Look approach to perception. According to this approach, perception is an active and constructive process influenced by many factors and values are one of the most important (Postman et al., 1948).

Rokeach's Theory of Values

Rokeach (1973) also conceptualized values within the framework of personality theory. In contrast to Allport, Rokeach adopted a cognitive approach. He viewed personality as composed of concentric subsystems of beliefs organized from the most central to the person to the most peripheral. The core subsystem of personality is the set of beliefs about oneself, with the next most central subsystems concerning their values.

Rokeach started a new tradition in psychological research on values by adopting Kluckhohn's (1951) view of values as explicit or implicit conceptions of the 'desirable.' These conceptions of the desirable may characterize groups as well as individuals. This reconnected the psychological study of values with its sociological roots and drew attention to the influence of social experience and location on value priorities.

Rokeach (1973: p. 5) defined values formally as "enduring beliefs that a specific mode of conduct or end state of existence is personally or socially preferable to an opposite or converse mode of conduct or end state of existence." By referring to values as beliefs about more and less preferred modes of conduct or end states, Rokeach conceptualized values as forming a hierarchical system. When referring to them as 'enduring,' he explained that values are acquired in an absolute, all-or-none manner that resists change, thereby insuring the continuity of personality. He held, however, that values do change through experience and processes of maturation in which absolute beliefs about the desirable come into conflict. Thus, his values approach makes it possible to consider a human being in terms of both permanence and changeability. Rokeach (1973) saw this changeability as an advantage of values over traits for describing personality, because traits presumably do not change. In sum, for Rokeach, beliefs are the main category for describing values and values are the basic unit for describing personality.

Rokeach criticized Allport because his list of values was too general; profiles on his six personality types profile could not distinguish adequately among the personalities of different people. Rokeach (1982) exemplified this problem by noting that two people for whom political values were dominant in their personality profile might be very dissimilar or even radically different if one of them embraced leftist values and the other rightist ones. This is an important criticism because it demonstrates that Allport's approach could not achieve its main objective, to describe individuals' personalities comprehensively and enable clear and informative interindividual comparison.

Rokeach (1973) sought to formulate a catalog of values that would be as complete as possible. Based on intuitive, theoretical, and empirical grounds, he estimated that the catalog of values held by people is not large. Rather than each person having a unique combination of values, people differ in the relative importance they attribute to the same limited set of values, that is, in their hierarchy of values. In other words, the same values guide all human beings, but their preference ranks differ. Rokeach proposed a list of 36 values, composed of an equal number of terminal or end-state values (e.g., wisdom, justice) and of instrumental or means/modes of conduct values (e.g., honest, ambitious). He used these categories in developing a measurement instrument entitled the *Rokeach Value Survey* (RVS) which consists of two lists, one of terminal values and the other of instrumental values. Respondents rank the 18 values in each list from most to least important as guiding principles in their own lives. Although the RVS presents the values as abstract terms with short definitions, the ranking of values is sufficiently specific to reveal subtle

differences in value hierarchies between individuals. This overcomes the weakness that Rokeach identified value surveys formulated in the Allport tradition. Hundreds of studies have employed the RVS to characterize and compare individuals and groups in an informative manner.

Schwartz's Theory of Values

Common Characteristics of Values in Different Theories

Schwartz (1992) defines values as transsituational goals, varying in importance, that serve as guiding principles in the life of a person or group. What differentiates among values is their motivational content. This definition integrates Rokeach's cognitive understanding of values as goals and Allport's motivational content of values derived from his view of values as both interests and evaluative attitudes.

Schwartz (1992, 2006) suggested that five characteristics of values are common to most previous psychological approaches to values: values (1) are beliefs linked to emotions; (2) refer to desirable goals that motivate action; (3) transcend specific actions and situations; (4) serve as standards for evaluating actions, policies, people, and events; and (5) form a relatively enduring hierarchical system ordered by importance. To this he added that (6) the impact of values on everyday decisions is rarely conscious, and (7) any action or attitude is guided by the relative importance of multiple, competing values, that is, by trade-offs among relevant values. Compared with values, attitudes are less abstract and less central to the self, relate to specific objects, derive their valence from the values that guide them, and do not serve as standards.

Circular Continuum of Values

Schwartz (1992) distinguished between the value hierarchies of individuals and the structure of relations among values themselves. Each individual has his or her unique hierarchy of values that determines the trade-offs that guide his or her behavior and attitudes. Schwartz's major innovation is his assumption that relations among different values have an inherent structure that is probably universal. He postulates that this structure takes the form of a circular motivational continuum (see Figure 1). Circularity expresses three features of the structure: adjacent values are motivationally compatible (e.g., security, tradition, and conformity), the similarity between values decreases with the distance between them around the circle, and motivationally opposed values are located on opposite sides of the circle (e.g., tradition opposes stimulation, self-direction, and hedonism).

Schwartz proposed three principles that explain the universal order of value relations around the circle. First, one can simultaneously pursue adjacent values in a single action (e.g., tradition and conformity by participating in religious rituals); adjacent values are compatible motivationally. Conversely, one cannot simultaneously pursue values located on opposite sides of the circle in the same action (e.g., climbing Everest as an expression of stimulation undermines security); opposite values are incompatible motivationally.

Viewing values as organized along two bipolar dimensions summarizes the oppositions between competing values. As the

Figure 1 The motivational continuum of values with the principles underlying their circular order. Modified version of the figure published in Schwartz, S.H., 1992. Universals in the content and structure of values: theoretical advances and empirical tests in 20 countries. In: Zanna, M. (Ed.), Advances in Experimental Social Psychology, vol. 25. Academic Press, London, pp. 1–65.

second circle from the middle of Figure 1 shows, one dimension contrasts *openness to change* and *conservation* values. This dimension captures the conflict between values that emphasize independence of thought, action, and feelings and readiness for change (self-direction, stimulation) and values that emphasize order, self-restriction, preservation of the past, and resistance to change (security, conformity, tradition). The second dimension contrasts *self-enhancement* and *self-transcendence* values. This dimension captures the conflict between values that emphasize concern for the welfare and interests of others (universalism, benevolence) and values that emphasize pursuit of one's own interests and relative success and dominance over others (power, achievement). The poles of these dimensions are called higher order values.

A second principle that organizes the value circle is the interests that value attainment serves. Values on the left of Figure 1 primarily regulate how one expresses personal interests and characteristics. Values on the right primarily regulate how one relates socially to others and affects their interests. Relations of values to anxiety are a third organizing principle. Values in the bottom part of the circle are based in the need to avoid or control anxiety and threat and to protect the self (Schwartz, 2006). Conservation values (bottom left) emphasize avoiding conflict, unpredictability, and change by submission and passive acceptance of the status quo. Power values (bottom right) emphasize overcoming sources of anxiety by actively controlling threat. In contrast, values in the top part of the circle are relatively anxiety free, expressing growth, and self-expansion. Self-transcendence values (top left) emphasize promoting the

welfare of others. Openness to change values (top right) emphasize autonomous, self-expressive experience. Achievement values do both: Successfully meeting social standards may control anxiety and it may affirm one's sense of competence.

One can segment a circular continuum in many ways (cf the color circle). Schwartz (1992) discriminated the 10 basic values and four higher order values in **Figure 1** arbitrarily, for scientific convenience. Most subsequent research has used these distinctions. **Table 1** lists the 10 values in their order around the circle, with a short definition of each.

Depending on one's objectives and the desired precision of one's tools, however, one can divide the continuum differently. A recent refinement of the Schwartz model partitions the same continuum into 19 more narrowly defined values whose effects are distinguishable (Schwartz et al., 2012). It distinguishes two types of self-direction (thought and action), two types of power (dominance and resources), two types of security (societal and personal), two types of conformity (rules and interpersonal), two types of benevolence (caring and dependability), and three types of universalism (nature, concern, and tolerance), plus two new values (face and humility).

Any catalog of values could be criticized as incomplete regardless of its theoretical bases. Researchers are bound to find new value concepts to add to the catalog of basic values as they study additional cultural groups. Thinking of values metaphorically as arrayed on a straight line, even if it is a continuum, one could always add new values at the ends of the line. The circular model is different because the space is closed and finite. Any supposedly new value must necessarily fit somewhere on the existing circle; it must represent some finer discrimination in the circle of motivations or a combination of recognized values. Adopting a conception of values as forming a circular motivational continuum has important, far-reaching implications. Four implications are particularly significant.

1. All the values that are recognized across human cultures are located on the motivational continuum of values.
2. The motivational continuum may be divided into as many or as few specific values as fit a researcher's objectives, but the relations among the values a researcher chooses are predetermined by the order of the circular continuum.
3. The structure of values consists of more than a list of values or groups of values. The circular arrangement reflects the similarities of adjacent elements of the circle and dissimilarities (or conflicts) between elements on opposite sides of the circle.
4. The structure of values provides a matrix that can reveal the motivational meaning of any particular value by examining its location relative to the other values in the circle.

Table 1 Ten basic individual values in the original theory, defined in terms of their core motivational goals

Basic value	*Core motivational goal*
Universalism	Understanding, appreciation, tolerance, and protection for the welfare of all people and for nature.
Benevolence	Preservation and enhancement of the welfare of people with whom one is in frequent personal contact.
Tradition	Respect, commitment, and acceptance of the customs and ideas that one's culture or religion imposes on the individual.
Conformity	Restraint of actions, inclinations, and impulses likely to upset or harm others and violate social expectations or norms.
Security	Safety, harmony and stability of society, of relationships, and of self.
Power	Social status and prestige, control or dominance over people and resources.
Achievement	Personal success through demonstrating competence according to social standards.
Hedonism	Pleasure and sensuous gratification for oneself.
Stimulation	Excitement, novelty, and challenge in life.
Self-direction	Independent thought and action choosing, creating, exploring.

Adapted from: Schwartz, S.H., 1992. Universals in the content and structure of values: theoretical advances and empirical tests in 20 countries. In: Zanna, M. (Ed.), Advances in Experimental Social Psychology, vol. 25. Academic Press, London, pp. 1–65.

Empirical Verification of the Circular Model of Values

Evidence supporting the circular model of values comes from cross-cultural studies with questionnaires designed to measure the 10 (or 19) values and from experimental studies and studies of value change. The questionnaires include the Schwartz Value Survey (Schwartz, 1992) that asks respondents to rate the importance of 57 abstract values as guiding principles in their life, three versions of the Portrait Values Questionnaire that ask respondents how similar they are to each of 21, 40, or 57 individuals who are described in terms of their important values (Schwartz, 2003, 2006; Schwartz et al., 2012), the Picture-Based Value Survey with 20 pictures that depict a child performing a value-relevant act which children rank for importance as they would like to be themselves using a five category Q-sort (Döring et al., 2010), and two types of forced-choice questionnaires in which respondents indicate which value is more and which less important to them as a guiding principle (Bilsky et al., 2012; Lee et al., 2008). Data using these different methods in over 75 countries, from hundreds of convenience samples and from some 40 national representative samples, support the circular value structure, although it is not always possible to discriminate among the adjacent values in the circle (Schwartz, 2011).

The circular structure implies that if a value becomes more important, values adjacent to it in the circle should also increase in importance whereas those opposed to it should lose importance. This pattern of structural change has been found both in laboratory experiments that employed value-priming interventions (Pakizeh et al., 2007; Maio et al., 2009) and in longitudinal studies in real life (Bardi et al., 2009). Maio (2010) summarizes additional experimental evidence to show that people represent values mentally in terms of the motivational conflicts and compatibilities the value circle depicts.

Values and Personality

McAdams and Pals' (2006) proposal to differentiate among three levels of personality provides a convenient framework to locate values in the personality structure. Their first level is consists of dispositional traits (usually Big Five personality traits), the second corresponds to cognitive and motivational constructs ('characteristic adaptations'), and the third concerns life narratives. Values might be located at the first or second level of this personality structure. At the first level, values can be viewed as a dynamic, motivational, aspect of personality. One could then draw a parallel between traits and values. Personality traits are biologically based formal characteristics of behavior, whereas values can be viewed as biologically based motivational tendencies (Cieciuch, 2012; McCrae, 2009). The biological basis of each may explain why studies across so many cultures support the Big Five traits and the value circle.

However, Schwartz (1992) follows Rokeach (1973) in arguing that values are cognitive/emotional transformations of needs or drives into goals. He grounded the values he identified in three universal requirements of human existence: needs of individuals as biological organisms, requisites of coordinated social interaction, and survival and welfare requirements of groups. Every value represents a goal that expresses at least one or more of these universal requirements (Schwartz, 1994). Values serve as socially acceptable terms that people use to communicate with others about their goals and to coordinate in pursuing them. Every person must cope with the universal requirements that underlie values. However, each person's unique biological heritage and social experiences combine to influence the relative importance assigned to each value, the person's own value hierarchy. Thus, values are characteristic adaptations shaped by the interplay of basic personality traits and the stimuli of the social and natural world.

Values and Behavior

Although many factors typically influence any specific behavior, values are often an important contributing factor. For values to be linked to behavior, they must be experienced as relevant. Because basic values are abstract, their relevance in particular situations is often not obvious. As Maio (2010) noted, people may see equality, for example, as relevant in situations of ethnic or gender diversity, but may fail to see it as relevant to discrimination based on weight. He proposed that people's abstract values relate more consistently to their behavior when they have 'concrete instantiations' of those values, that is, when they have thought of specific ways in which a value is or can be expressed in real-life situations. Maio (2010) summarizes series of experiments which demonstrate that values affect behavior more when people have thought about tangible applications of those values and when those applications are typical (gender equality) rather than atypical (handedness equality). Typicality makes people perceptually ready to 'see' a value as relevant in subsequent situations.

Several mechanisms link values to behavior (Bardi and Schwartz, 2003; Schwartz, 2009). First, values influence choices because people act in order to attain, affirm, or preserve the goals that their important values express. For example, people vote for parties whose platforms facilitate attaining the values they cherish and against parties whose platforms threaten attainment or preservation of these values (Caprara et al., 2006). Put differently, people's values determine the valence that people assign to the consequences of any action. Actions are more attractive, more subjectively positive, to the extent that they promote attainment of valued goals. The value-based assessments of potential choices typically occur outside of conscious awareness. Values enter awareness when the actions, one is considering, have conflicting implications for different values one cherishes.

Second, values influence behavior through their effects on planning. The higher the priority given to a value, the more likely people will be to form action plans that can lead to its expression. Planning focuses people on the pros of desired actions rather than the cons. It increases people's belief in their ability to reach the valued goal, their persistence in the face of obstacles and distractions, and their belief in the desirability of the goal. By promoting planning, value importance increases value-consistent behavior.

Third, values influence behavior through their effect on attention, perception, and interpretation in situations. People attend more to those aspects of situations that threaten or offer opportunities to attain their cherished values. One person may perceive a job offer as an opportunity for greater self-direction, another as a threat to her security. One may interpret the offer as a chance to help his family, another as a chance to gain power and influence. Each value-based perception or interpretation suggests that a different line of action is desirable.

Values on the Boundary of Psychology

The approaches discussed above treat values as characteristics of individuals, thereby placing value theories in mainstream psychology. Value priorities are also used to describe and compare societies and cultures. Research on societal or cultural values usually aggregates the values of group members to obtain mean priorities (e.g., Inglehart and Baker, 2000). Theories differ in whether they view cultural values as located in the minds of individuals (e.g., Hofstede, 2000) or as hypothetical, latent variables that support and justify the functioning of societal institutions (Schwartz, 2011). This research primarily investigates effects of cultural values on individual attitudes, beliefs, and behavior, and relations of cultural values to other characteristics of groups and societies (affluence, social policies, socioeconomic change, etc.). Thus, the study of values extends out from psychology to all of the social sciences.

Abstract

The first section of this article presents core elements in the object- or concept-focused definition of values, including some of the functions ascribed to them: guiding and coordinating actions, marking personal and collective identities. The next section introduces some additional analytical dimensions: the substantive, temporal, and social generalization of values; their position in means–ends relationships; conceptual distinctions with regard to needs, attitudes, and norms. The third section addresses some issues regarding the development of values on the personal and macrosocial level, concentrating on the cognitive developmental approach. The final section presents a brief outline of two prominent approaches (initiated by Inglehart and Schwartz) in studying the development and spread of values on the basis of data collected in a long-term series of cross-national surveys conducted in an increasing number of countries worldwide.

Values are generally considered to play a crucial role in motivating and guiding human action and to be constitutive elements in the construction of personal and collective identities; they serve as a potent source of social integration but also of conflict and division. Values are conceptualized quite differently in various sociological theories. This article focuses on those analytical distinctions and fundamental assumptions that are widely shared among sociologists and other social scientists, but some of the issues on which theoretical perspectives diverge will also be mentioned.

What Are 'Values,' How to Define Them?

There are numerous definitions – or rather explications of meaning – available in the sociological literature. Most of them can be classified into two groups: (1) 'values' as something directly attached or ascribed to preferred objects and (2) 'values' as (enduring) beliefs or conceptions that construe something as preferable or desirable. The first approach is exemplified by Thomas and Znaniecki (1958: p. 21) who write: "By a social value we understand any datum having an empirical content accessible to the members of some social group and a meaning with regard to which it is or may be an object of activity. Thus, a foodstuff, an instrument, a coin, a piece of poetry, a university, a myth, a scientific theory, are social values." In a similar vain, R.H. Turner (1968: p. 100) states: "A value is a category of objects…." The second approach, which has become the dominant one within sociology (in contrast to economic theory), is represented by C. Kluckhohn (1951: p. 395) who, drawing upon Dewey, writes: "A value is a conception, explicit or implicit, distinctive of an individual or characteristic of a group, of the desirable which influences the selection from available modes, means, and ends of action." And he emphasizes, "that affective ('desirable'), cognitive ('conception'), and conative ('selection') elements are all essential to this notion of *value*" (ibid.).

The crucial point here is the distinction between something simply desired (matter-of-factly) and something conceived to be desirable, based on some reasoned judgment. An object may be desired directly as such for whatever qualities it innately has (or is assumed to have). But in order to 'value' an object – according to Kluckhohn's conception – it must fulfill certain criteria that transcend it. This transfer of meaning, however, may advance into something like a transformation of the object: it may take on a symbolic quality, which makes it appear and then be treated as a value in itself, while its connection to some 'conception' of desirability might recede in the background; patriots, for example, may endow the national flag with such a quality. Thus, the object-focused and the concept-focused definitions are commensurate to some extent: a value may be instantiated in or symbolically represented by some object or behavior, which in turn becomes indicative of the value construct.

There is an element of circularity in Kluckhohn's definition: how can desirability be stated without referring to preconceived values? This circularity can be mitigated by interpreting values as 'second-order' desires (H.G. Frankfurt) and explicating the experiences and processes by which values are generated or arrived at. A first-order desire can be conceived as some want (drive, urge, impulse), directed toward some object that is given independently from any judgment regarding its appropriateness. We may act upon this want spontaneously. But since we experience different sorts of such first-order desires, some of them competing with each other and with those of other people, we are led into reflections seeking or constructing criteria that enable us to evaluate and rank order our desires, abstracting and transforming them into second-order desires and, in an additional step, into a second-order volition. Of course, there is always the possibility of getting overwhelmed by our spontaneous urges and desires.

The evaluative standards applied in such processes comprise different elements; Parsons, for example, distinguishes cognitive, appreciative, and moral standards (Parsons and Shils, 1951: pp. 162ff.), and Kluckhohn (1951: p. 397) emphasizes that "the consistent connection between values and notions of approval and disapproval implies the potentiality for rational justification"; he also sees a "union of reason and feeling inherent in the word *value* (ibid., 400)." The meaning of such

evaluative standards is revealed in binary (or bipolar) codes in terms of which judgments are being made – like 'good' vs 'evil/bad' (in the case of moral standards), or 'true' vs 'false' (cognitive standards), 'beautiful' vs 'ugly' (aesthetic standards). Some of these codes may be applied reflexively. For example, one may judge it as good or bad (right or wrong) to deliver or not deliver a moral judgment (in terms of good or bad) in a specific situation; moralizing, however, might be considered inappropriate with regard to certain issues in certain social contexts. We thus move from second- to higher-order desires. The 'moral matrix,' i.e., the set of issues or dimensions requiring or allowing for moral judgment varies between cultures and among social groups (Haidt, 2012).

Any culture offers to the person a repertoire of evaluative standards, *social* values; they are conveyed and inculcated, over various stages of development, via socialization processes and supported by social practices and interaction rituals (Durkheim, Collins), but they also need to be interpreted individually and variedly depending on the specifics of the situational context in which they are employed. A single act normally touches upon various (and often competing) values (like honesty and politeness); on the other hand, a single value may be related to a larger set of actions. Values thus come into play not singularly but as a plurality, which means they must somehow be harmonized, arranged into a value 'system' or comprehensive sets of value orientations in which they are hierarchically ordered, to some extent at least. Such an arrangement, however, must also allow for a considerable degree of flexibility, it must remain open for context-specific interpretations and modifications over time. In this sense, values are enduring but not static.

As cited above, Kluckhohn defines values as "distinctive of an individual or characteristic of a group"; as such they may serve as markers of personal and collective identity. On whatever level of social generalization values are analytically located, for most sociologists the concept contains an element of normativeness. Desirability implies a notion of shared beliefs and commitments, including a commitment to one's true self, which incorporates the perspective of a 'generalized other' (Mead). The striving to realize some value is thus connected with a sense of oughtness, something requested from oneself and from others, a request that, if not met, may elicit guilt and shame feelings (imposed upon oneself) or indignation and despise (at someone else), or, if met, pride and respect. The reach and intensity of the ought component varies; there are values considered to be (more or less) 'private,' at one's personal disposal, others (particularly moral values) are more or less obligatory, and placed under public control.

Kluckhohn includes, as we have seen, a functional description in his definition of values by stating that "[a] value influences the selection from available modes, means, and ends of action." Some additional functions can be added here (for a longer list see Rokeach, 1973: pp. 12–16): (1) Values not only guide actions (though they are, by far, not the sole determinant), they also influence perceptions and feeling states. (2) They provide a 'vocabulary of motives' (Gerth and Mills, 1953), which helps to make sense of and to interpret, explain, justify, or criticize one's own as well as other people's behavior, prospectively and retrospectively. (3) Shared (social) values provide a base for commonalities and trustful communication; they stabilize expectations needed to coordinate interaction over the long run. They perform these functions to the extent that they are uncontested. "They can be taken for granted and this taken-for-grantedness can also be taken for granted" (Luhmann, 1996: p. 31). In other situations, however, values can also be disputed among persons and groups and thus instigate conflicts.

Some Further Analytical Dimensions and Distinctions

Dimensions of Generalization

As concepts, values are symbolically (re-)presented by words, behavior (e.g., gestures and rituals), and visible objects (e.g., badges or monuments). As symbols, they "involve 'interpersonalizing' the kind of 'abstraction' or 'generalization' which characterizes all stable systems of orientation" (Parsons and Shils, 1951: p. 161). Luhmann (1998: pp. 340f.) conceives of values as 'symbolically generalized media of communication,' and he distinguishes three interdependent dimensions of generalization: the substantive, the temporal, and the social.

The first dimension refers to the delimitation of semantic meaning, the substantive content, and thematic unity of the concept, which is specified by some contrast or difference: what pertains to it and what is excluded, e.g., equality vs inequality, respect vs disrespect, granted to whom and whom not. The semantic meaning of a value concept can be abstracted to lower or higher levels and specified across many or not so many situations and institutional contexts.

The temporal generalization is brought about by various forms of custom building and habit forming or by explicit norm setting. Particularly, the norms connected with or inherent in values lend certainty and stability to expectations derived from them: In case of disappointment it is not the expectation that needs to be corrected, rather the perpetrator is in the wrong (on the distinction between norms and values see below). Value surveys often fail to adequately capture the element of normativity tight up with values.

Social generalization seems to be an obvious ingredient of values. They are shared among different persons – but shared to what extent? On the lower end of the scale we have 'personal' or 'privatized' values, shared by only a few people; or they may be held in common by many people but unknowingly so and/or without any normative request. 'Social' generalization is thus intimately linked with temporal or normative generalization, and there are at least two subdimensions that need to be distinguished here. One is the factual range of agreement (consensus) or disagreement (dissent), the other is the assumed or perceived range of consensus or dissent. Perceived and factual agreement may fall apart in both directions. People not only act on their own attitudes and personal values, but also on what they perceive to be other people's beliefs and values. Unfortunately, empirical value surveys usually limit themselves to registering only the degree of factual consensus (by aggregating individual data, calculating means and variances); they regularly fail to ascertain at least the first level of reciprocity, i.e., their respondents' perceptions of what other people think and value (more on this and normativity in Thome, 2003).

Instrumental and Terminal Values, Empirical and Transcendental Ends

In his famous book on *The Nature of Human Values*, Rokeach (1973: pp. 7f.) distinguishes between 'instrumental' and 'terminal' values; in the same sense he also speaks of 'means and ends values.' The former refers to 'modes of conduct' (e.g., being 'ambitious,' 'self-controlled,' 'independent'), which are thought to be instrumental in attaining the latter, also referred to as 'end-states of existence,' like 'happiness,' 'freedom,' 'salvation,' or 'self-respect' (ibid., 12). When Rokeach considers all 'moral' values (like 'honesty') to form a subgroup within the category of instrumental values, his conception runs counter to what many other scholars construe as moral values. He acknowledges the possibility "that one terminal value, so defined, is instrumental to another terminal value or that an instrumental value is instrumental to another instrumental value" (ibid.), but his focus lies on the assumption that there is a certain type, a fixed set of values, which are all instrumental to a second type of values, the 'terminal' ones, which in turn cannot (by definition) be employed as means to attain an 'instrumental' value.

Parsons' conception of 'means–ends chains' is more flexible on this: "concrete action does not take place in terms of isolated ends with only one set of means, but rather in terms of very long and complex 'chains' of means-end relationships, so constituted that the 'end' of one sector of the chain is a means to some further end (or more than one)" (Parsons, 1990: p. 322). The ultimate ends (Parsons also speaks of 'ultimate ends or values,' p. 323) envisioned or gradually emerging (in the course of action) can be 'empirical' or 'transcendental.' Whether or not an empirical end is reached (by causally adequate means) can be checked by the actor and by an outside observer. Whether or not a transcendental end has been attained is not arguable by an external observer in terms of scientific criteria. In this case, the means–ends *relationship* becomes 'symbolic,' e.g., when people perform religious rituals. The 'symbolic appropriateness' attributable to this relationship can be interpreted by an external observer, it does not need to be explicitly conscious to the actor himself (Parsons, 1968: p. 258).

Means–ends relationships are often looked at in only one direction: what has been attained as an end can, in the next step, be employed as a means to reach another end. But Simmel already pointed out that originally trivial means can be turned into (ultimate) ends, referring to money as a striking example.

Related Concepts: Needs, Attitudes, and Norms

Needs

Needs are generally conceived as more or less urgent wants or desires, which are registered or make themselves felt as such by the actor herself/himself or by an observer. They can be given independently from any evaluation (i.e., they are 'first-order desires'), though the way they are shaped and perceived (e.g., as necessities that assure survival in a natural and social environment) is likely to be influenced by some evaluative reflections or other external considerations. Often they are seen as rooted in the organic system (physiological processes) or in 'human nature' (including its social embeddedness), independent from one's volition. There are different conceptions concerning the interconnectedness of needs and values. They can be conceived as the input, the raw material from which values are abstracted. Ball-Rokeach and Loges (1992: pp. 2222f.) contend that "(v)alues are cognitive representations of human needs … [they] unite individual's needs with the broader needs of society." Kluckhohn (1951: pp. 428f.) states: "Values *both* rise from and create needs", but he also notes that "some choices do not involve value elements but solely need elements." The (relative) urgency of needs (depending on their respective level of satisfaction) changes with changing natural environments, technologies, and social conditions; needs may thus serve as a mediating factor in the development of values.

Attitudes

Thomas and Znaniecki (1958: p. 22) define *attitude* as "individual consciousness which determines real or possible activity of the individual…. The attitude is thus the individual counterpart of the social value." Kluckhohn (1951: p. 423), too, emphasizes the 'exclusive referability to the individual' as a core definitional element in the concept of 'attitude,' but he adds a second 'principal difference from *value*' namely "absence of imputation of the 'desirable.'" Though 'attitude' implies a positive, negative, or indifferent stance taken toward some object, for whatever reason, the concept as such implies no element of oughtness. Attitudes may engage values, but values may also become the object of an attitude.

Norms

Norms are generally defined as (formally or informally given) rules about what persons – in most cases a specified set of persons – ought to do or not to do in given circumstances, enforced by the threat of sanctions in the case of transgression. In contrast, values inspire and guide behavior, but they are quite independent of specific situations, and they do not directly prescribe or proscribe a specific behavior. Norms are restrictive in their sheer oughtness; values instead are enhancing, they inspire a striving for something 'greater than oneself' (see the concluding paragraph in the third section below).

Values are regularly employed to justify and legitimate norms, but it can be misleading to say of norms (making it a part of their definition) that they 'specify' values, or that they are 'derived' from them. Norms are needed to coordinate action and maintain social order particularly in circumstances where the actors involved hold different or conflicting values. To perform this function (especially in highly differentiated societies), there must be available a repertoire of (mainly legal) norms that are neutral with regard to any set of potentially conflictive particularistic values (see the long-standing discussions about the nature of 'positive' law and the relationship between legitimacy and legality). The construal of more highly abstracted values that transcend the apparent discrepancies between more concretely specified values may also help to prevent or mitigate conflict. Individuals who are in disagreement with norms that are imposed upon them might still decide to obey them, not only for fear of sanctions but also because they have made their compliance to legitimately established common or legal norms, a higher-order norm (a principle) that they are willing to adhere to in order to serve the (universally) valued goal of peaceful coordination of

action, whatever conflicts might arise on the level of lower-order values. When norms are highly abstracted and formulated as principles, the analytical difference to values might get blurred. These constellations have also triggered much theoretical debate among philosophers and social scientists seeking to clarify the priority relationship between the 'right' and the 'good.'

Developmental Perspectives: Adopting, Generating, and Changing Values

The adoption and reconstruction of values on the personal level and in different stages of life have mainly been conceptualized and studied as a major element in processes of socialization shaped by the given and further evolving (sub-) cultural systems and by their respective location within the differentiated structure of social systems. These processes have been theorized in widely differing ways by psychologists and social scientists. In this section, I will concentrate on core concepts of the cognitive developmental approach, which focuses on moral norms and values and has its major roots in the work of Kohlberg. This approach is particularly interesting because it offers hypotheses and empirical insights not only on personal development, but also relates these processes to certain features of large-scale societal structures that have been evolving in recent history. At the end of this section, I will briefly point out a rather different approach, which conceives of identity-constitutive values as arising out of emotion-laden 'experiences of self-transcendence.'

Kohlberg (1981, 1984) describes individual moral development as a sequence of three major (and further subdivided) stages characterized by rising levels of (cognitive) understanding and different types of conformity motives. At the 'preconventional level,' norms are taken to be valid because they are (re-)presented by authorities; they are followed in order to avoid punishment or receive rewards. At the 'conventional level,' moral values and the norms associated with them are deemed valid because they are propagated in one's group or society; they are primarily accepted and obeyed in order to gain social acceptance and to avert guilt feelings. At the 'postconventional level,' reached by a smaller portion of people, individuals ascribe superior validity to universal moral principles (centered around the concepts of justice and fairness and equal basic worth of all human beings), which they respect and voluntarily submit to on the basis of reasoned insight in their legitimacy. The major factor propelling forward this movement from one stage to the next, Kohlberg (taking the lead from Piaget) saw in the developmental 'logic' inherent in the ontogenetic advancement of cognitive capacities from early childhood into adolescence. He also assumed a gradually increasing consistency between the cognitive and the motivational dimension of moral development, between judgments (concerning the rightness of moral norms and the validity of moral values) and the willingness (motivation) to act in accordance with them.

More recent research has led to several modifications and additional analytic distinctions. A major correction achieved herein was to differentiate and disentangle the cognitive and the motivational dimension – moral understanding and moral motivation are now seen as independent dimensions (Colby and Damon, 1995; Nunner-Winkler, 2004: pp. 306f.). Each level of cognitive moral understanding can be associated with different types and varied strength of moral motivation, though some (correlational) affinity between these dimensions seems to persist. A high level of moral understanding might be tied up with a high level of moral motivation: acting morally may become a central part of a person's self-identity; but it can also be associated with a low level of motivation or with an inclination to make use of 'neutralization techniques' and cognitive distortions, which pave the way to moral disengagement (Bandura et al., 1996). There is also some debate on whether or not or in which way such a 'minimalized' set of highly abstracted and universally valid moral principles (most essentially: not to inflict harm on other people) can be or in fact are supplemented with more concretely prescribed moral rules associated with broader sets of values concerning the 'good life' as perceived and construed within particular communities of varied size and social location (see, e.g., Joas, 2000).

Nunner-Winkler (2004) registers a large-scale historical trend in societal development that has strengthened the advancement toward higher levels of moral reasoning reached by a growing number of individual persons. Her starting point is Elias' claim that there is a coevolution of societal and personality structure (Elias, 1994). In these processes, chains of interdependence among increasing numbers of interacting persons, institutions, and administrative units were elongated, thus calling for ever more individual insight and considerateness, i.e., self-control. Consequently, 'outside constraints' (level 1 in Kohlberg's developmental theory) were more and more replaced by internalized 'self-constraints' (level 2). Many other theoretical models for analyzing long-term societal developments could be introduced at this point, e.g., Durkheim's ideas on the erosion of collectivism; Weber's propositions concerning the increasing and multifaceted import of processes of rationalization; Riesman's theses on the shifting weights of tradition-, inner-, and outer-directed orientations as characteristic features of evolving cultures and personality structures; more recent work by Wouters (1986) has emphasized the increasing importance of processes of 'informalization.' Most theorists are agreed upon assuming that societies in the long run have become less hierarchically organized and more differentiated into interdependent subsystems performing specialized functions more or less autonomously and reaching out beyond national boundaries. These processes – including the dismantling of hierarchical structures within the family – have made individuals become increasingly more autonomous: free, but also forced, to make their own choices, free to enter cooperative relationships but also pushed to develop their competitive capacities. According to Nunner-Winkler (and others), the sociohistorical changes in societal structure and in socialization styles have, on the level of individual personalities, promoted the transition from the second to the third level of Kohlberg's scheme of moral development: "a change from super-ego controls and habitualized conformity dispositions towards more ego-syntonic types of conformity motivations" (Nunner-Winkler, 2004: pp. 309f.). But she also warns that "there might be a rising risk that the increasing availability of ego-syntonic

conformity motivation might go along with the dismantling of previously reliable barriers against amorality" (Nunner-Winkler, 2000: p. 239). The structurally induced release from moral bind has been a central topic in theories of anomie, with a broad range of empirical evidence particularly produced in studies of crime development (see, e.g., Messner et al., 2008).

As indicated above, cognitive developmental theories assume that on the highest level of personal moral development high-conformity motives, i.e., the willingness to act in accordance with moral values and norms considered universally valid, emanates directly from one's reasoned insight into what is 'right.' Other scholars have argued that rational reflections as such cannot produce motivation, that there is no motivation without the press of emotions. Joas (2000), drawing on Ch. Taylor and others, expounds the idea that motivating conceptions of the desirable are anchored in and ultimately emerge from emotion-laden experiences of self-transcendence, in which a person is captivated by something that carries her beyond her personal self, without losing it. Such (elevating, but in other cases dejecting) experiences are evoked when smoothly proceeding routine activities of everyday life get interrupted or turned into a new and unexpected direction, thus calling into question previous paths of behavior and hitherto held beliefs and interpretations. Examples are religious revelations, falling in love, loosing one's job, getting intensely praised or humiliated, having a friend dying in an accident, being suddenly confronted with the misery of other people. The elevating or disturbing feelings elicited in such situations call for articulation and narration in order to find new interpretations that clarify, partially revise and partially confirm, one's own standing on what is good or bad (values) and how this is related to what is right or wrong (in terms of norms). In this perspective, the adequacy of norms can be judged rationally (with regard to their efficiency in coordinating social action), the validity of values, however, is comprehended in the interplay of reflections and emotions arising from elevating or disturbing experiences that press for articulation and interpretation (for a challenging view on the role of emotions in grounding moral values see De Sousa, 2008).

Empirical Research on Values and Value Change

There is a long tradition of empirical studies on values and value change, in which a large array of strategies and techniques has been used to collect information and interpret data from all sorts of written text, from participant and nonparticipant observation, from face-to-face interviews or questionnaire responses. A brief overview of empirical value studies of various types produced till the early 1980s is offered by Spates (1983). To study values in national and cross-national perspective, large-scale survey studies based on representative samples of whole populations (or of specific subpopulations like highly qualified employees of large corporations, school teachers, or university students) and repeated overtime have become the prime research instrument. Since the 1970s, sociological discussions on value change have been increasingly dominated by the work of Inglehart (e.g., 1977, 1997) and the *European* and *World Values Surveys* he has initiated. Since the mid-1990s, another approach on cross-cultural value research developed by S.H. Schwartz, has received increasing attention as well. What follows here is a brief outline of the major concepts and empirical findings advanced in both of these research groups (with respect to Inglehart, I draw upon a more comprehensive review in Thome, 2008). I also want at least to mention the cross-cultural studies by Hofstede (1980, 2001) and by Triandis (1995) as well as the values research based on experimental gaming strategies applied in a laboratory setting (see, e.g., Wilke et al., 1986), which I cannot review here due to space limitations (for an overview on these approaches see Karp, 2000).

Inglehart is best known for his interpretation of value change (since the late 1960s) as a shift in preferences away from 'materialist' to 'postmaterialist' values. His initial hypotheses were derived from Maslow's theses on need hierarchies (Maslow, 1954) stating that "people act to fulfill a number of different needs, which are pursued in hierarchical order, according to their relative urgency for survival" (Inglehart, 1997: p. 22). On this view, the physical need for sustenance and freedom from bodily harm takes precedence over all else. Only to the extent that these are satisfied do we, according to these assumptions, turn our attention to the social need to belong and to be respected, and finally to the personal need for self-actualization. With respect to political objectives (Inglehart's primary value indicators), basic needs find expression, for example, in the pursuit of economic stability and continuous growth; the need for security requires public order and protection from criminality and (seemingly) hostile countries; the need to belong and to be given respect motivates calls for participation in the workplace and in politics; self-actualization requires legally enshrined freedoms and opportunities to arrange our lives as we see fit. Inglehart's idea was to ask people how urgent they considered political goals he presented to them via questionnaire items classified in this way as indicating a stronger or weaker leaning toward the materialist or postmaterialist pole of such value orientations. The item batteries that Inglehart had designed to measure value orientations via a rank ordering of political goals were included in the *Eurobarometer Surveys* (EBS) conducted on behalf of the European Commission since 1973 twice a year (the data are available as an online trend file, see references below, which also includes data from three earlier European surveys as well). In addition to the EBS, Inglehart et al. initiated more comprehensive *European Values Studies* and *World Values Surveys* starting in 1981, now in its sixth wave scheduled to be concluded in March 2014. These surveys have by now covered about hundred countries in all continents.

The European data till (roughly) 1990 confirmed, by and large, Inglehart's prognoses concerning the shift toward postmaterialism in central European countries. Since then the trends diverged cross nationally, and despite further economic growth postmaterialism declined in several countries. There was (and still is) considerable debate not only on Inglehart's way of theorizing, but also on the adequacy of his instruments of measurement (see, e.g., Clarke, 2000; Flanagan, 1987; Vinken, 2006), which have become increasingly questionable as the surveys were expanded

to include non-European countries as well. Inglehart himself has extended his system for categorizing relevant value orientations. The dimension of materialism vs postmaterialism has been embedded in the more broadly conceived dimension of 'survival vs self-expression,' which includes additional measurements of subjective well-being, trust in other people, political engagement, and tolerance for nonconformist lifestyles. The ensuing research has made increasingly clear that there has not been a departure from materialist values but rather an increasing emphasis on combining economic prosperity with libertarian, antiauthoritarian value orientations (Welzel, 2009). Inglehart has also constructed a second analytical dimension, which contrasts 'traditional' and 'secular-rational' orientations (Inglehart and Baker, 2000; Inglehart and Welzel, 2010). Key points here are belief in God and religious commitments, respect for authorities, regard for one's own nation and the family. Inglehart acknowledges in principle that these two dimensions may be combined in different ways in different countries. While a continuous increase in economic prosperity promotes both secularization and self-expression values, this development is 'path dependent,' considerably determined by cultural traditions. Nevertheless, for the long run he sees both dimensions converge into a two-stage process of 'modernization': Traditional values are replaced (or dominated) by secular-rational values in the process of industrialization; self-expression values become predominant during the transition from industrial to postindustrial (postmodern) societies. More recently, this approach has been further expanded and modified into a 'human development model' (Welzel and Inglehart, 2010).

Inglehart's ordering of countries from all continents along these two analytical dimensions is, in its overall configuration, pretty much what one might expect. European countries with large portions of Protestants load high on both analytical dimensions, those with large portions of Catholics are located around the center, whereas South-Asian and Islamic countries rank low on both dimensions. However, it appears highly problematic (in some cases at least, e.g., when inquiring religious beliefs) to use identical questionnaire items in very different cultural regions. More generally, it is highly problematic to use questionnaire items (as Inglehart does), which address different categories of values on rather different levels of analytical abstraction and specificity. Also, the rankings of a set of value items (particularly if specified as political goals) might be strongly influenced not just by the degree of desirability ascribed to them, but also by the degree to which respondents consider them to be at risk or rather fulfilled under given circumstances. These assessments should therefore also be explicitly measured in these surveys and statistically controlled for when evaluating priority rankings of values (cf Thome, 2003).

A theoretically and methodologically more elaborated system of value categories and survey instruments applied in cross-cultural studies has been worked out by the social psychologist S. H. Schwartz (drawing on Hofstede, 1980). He has proposed a system of 10 basic value types, each specified by individual-level motivational emphasis and translated into a set of more than 50 personal goals (Schwartz, 1994): power, achievement, hedonism, stimulation, self-direction, universalism, benevolence, tradition, conformity, security. According to Schwartz, these values represent three 'universal requirements of human existence,' which he does not rank in advance: needs of individuals as biological organisms, coordinated social interaction, survival, and welfare needs of groups. Surveys conducted in a set of 66 nations proved 45 of the 56 (occasionally 57) value items to have similar meanings across nations (Schwartz, 2004). The 10 basic values are grouped along two higher-order bipolar dimensions: the first contrasts 'openness to change' (seeking stimulation and self-direction) with 'conservation' values (seeking security and conformity, upholding tradition), the second opposes 'self-transcendence' (orientation toward universalism and benevolence) with 'self-enhancement' (seeking achievement and power); the tenth value, hedonism, cuts across the borderlines between self-enhancement and openeness to change. Thus, the 10 basic values can be ordered to be more congruent or more opposing to each other, rather close or rather remote in their meaning. Schwartz (1994: p. 97) sees the cultural and the individual level of values conceptually related, but he also points to specific cultural differences in dealing with 'critical issues that confront all societies.' He classifies these into three bipolar dimensions referring to the relative weight given to (a): 'embeddedness' vs affective or intellectual 'autonomy' (of individuals in relation to social groups), (b) 'hierarchy' vs 'egalitarianism' (with respect to social status and power distribution), and (c) 'harmony' vs 'mastery' (striving for peace and for unity with nature, or for self-assertion in attaining group or personal goals) (Schwartz, 2004: pp. 45f.). This scheme thus comprises seven categories of opposed or supplementary cultural orientations. Schwartz sees the validity of this scheme confirmed by empirical analyses based on data collected on those 45 value items that were found to have similar meanings across nations and cultures. For 67 nations and cultural groups (represented by teacher and student samples), the mean scores for each of these items were registered and pairwise correlated. Multidimensional scaling analyses were then performed to map the cultural differences between nations. In this way Schwartz identified seven transnational cultural groupings, which show 'striking parallels' with the clusters found by Inglehart (based on different analytical dimensions). So, for example, West European countries load high on autonomy, egalitarianism, and harmony, whereas Confucian countries lean toward the opposite pole on all of these dimensions: embeddedness, hierarchy, and mastery.

Schwartz et al. (2001) also developed a second measurement instrument, the 40-item 'Portrait Values Questionnaire' (PVQ), which demands lower levels of abstract thinking so that it can be used in large population surveys not limited (like the original instrument) to samples of highly educated people. This instrument, too, has been validated across many cultures. To be included in the series of *European Social Surveys* (ESS) starting (with 2 years interval) in 2002/03, a shortened, 21-items version of the PVQ has also been set up. In the meantime it has been shown, however, that this instrument

does not represent the full range of the 10 value types identified before (Meuleman et al., 2012). A thoroughly conducted comparative assessment of the validity of both the Inglehart and the Schwartz value theories is offered by Datler et al. (2013).

Abstract

Thorstein Veblen witnessed significant changes in the American political, economic, and cultural landscape. Industrialization replaced agriculture as the primary source of income for the American economy. Urban population centers flourished, and across the country, politicians debated social justice initiatives. The writings of the 'muckrakers' informed and mobilized the general public to action regarding unfair business practices and corrupt political elites. Veblen also witnessed the rise of the corporation and spread of unprecedented economic disparities.

The Theory of the Leisure Class was Thorstein Veblen's most popular work. He was a prolific writer in both economics and sociology. To better understand his writings, Veblen must be located in history and the traditions of his community. In his lifetime, the United States fought three wars: the Civil War, the Spanish–American War, and World War I. Veblen lived during a time when Charles Darwin's theory of the origin of species was groundbreaking. Herbert Spencer's application of natural selection or 'survival of the fittest' to explain social stratification supported the viewpoints of neoclassical economists. These apologists of business interests advised against any regulation or interference with the 'hidden hand of the market.' In addition, Spencer's schema justified a lack of humanity or compassion for those who did not possess wealth. The shift in America's economic engine from agriculture to manufacturing paved the way for European immigration required to meet manufacturing demands. Urbanization weakened individuals' ties to their faith, family, and community. A new social order was emerging that would have a profound effect on several generations that followed.

Veblen's contemporaries include the 'fathers' of American pragmatism – Charles Peirce, William James, and John Dewey. Their ideas considerably influenced Veblen's convictions regarding social justice and humanistic philosophy. William Sumner also had an impact on Veblen's theory of the evolution of social systems. Though Veblen never supported Marxism, because of his radical stances, he is often referred to as the 'American' Marx (Mitchell, 2001).

Family Background and Early Life

Thorstein Veblen was born on 30 July 1857 in Manitowoc County, Wisconsin. His parents, Thomas and Kari Veblen, immigrated to America from Norway in 1847. They eventually saved enough money to purchase a 290-acre farm in Minnesota that became the family's permanent homestead. Thorstein Veblen took after his father, a respected leader of a small farming community. He respected his father's views on social order and injustice, but unlike his father, Veblen was precocious; he tested the limits of prescribed behavior in his austere Norwegian community. When Veblen had reached a mature age, his father arranged for him to attend Carleton College. Thorstein was never consulted on the matter, and perhaps this is one of the reasons why he struggled with accepting the doctrines and Christian values of the College.

After graduating, Veblen briefly attended Johns Hopkins University. There he met Charles Peirce, who first introduced him to American pragmatist ideas. After a brief stint at Johns Hopkins, Veblen moved to Yale to study under the tutelage of William Sumner, a scientist who embraced Darwinism and the views of the British sociologist Herbert Spencer. Through Sumner, Herbert Spencer's ideas took on a form that was to be important and influential in Veblen's work (Hess, 2001).

Veblen received a PhD degree in philosophy from Yale in 1884. However, he was subsequently unable to find a faculty position, perhaps because of his Norwegian descent or his unwillingness to adhere to the teachings of the Christian faith. When he returned to his parents' community in Minnesota, Veblen reported that he was ill and needed time to recuperate. During his recuperation, he devoted his time to reading and studying botany. He also found time to court Ellen Rolfe, whom he married in 1888.

In 1891, Veblen enrolled as a graduate student in economics at Cornell. He received a graduate fellowship to study with Laurence Laughlin, and in 1892, he followed Laughlin to the University of Chicago. At Chicago, he was introduced to the works of William James and John Dewey; James' theory on 'habit' and 'instinct' would later come to influence many of Veblen's published works.

After rumors of marital infidelity, in 1906, Veblen decided to move to Stanford University in California, where he had been offered an appointment as associate professor in economics. However, due to his unpopularity as a teacher and dissatisfaction with the institution, he resigned the post in 1910. In 1911, he accepted an appointment at the University of Missouri–Columbia but soon resigned his position there to move to the east coast to work for the Food Administration in Washington, DC. Veblen found working in a government bureaucracy vexing and left the agency in 1918. In the fall of the same year, he joined the editorial staff of *The Dial*, a radical journal of literary and political opinion located in New York City. He also started to collaborate with Charles Beard, James Harvey Robinson, and John Dewey to establish the New School for Social Research. After his retirement in 1926, Veblen moved

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61309-0

back to California, where he lived in a cabin near Stanford University. He died there in 1929.

The Gilded Age

The term Gilded Age was coined by Mark Twain and Charles Dudley Warner in their book, *The Gilded Age: A Tale of Today* (1873). The book satirized the rising inequality between economic classes and the apparent lack of interest among government officials concerning the consequences of their laissez-faire policies. By the turn of the nineteenth century, America's industrial production outpaced England, Germany, and France combined. The result of this growth was a bifurcation of income and social class. A few large corporations dominated the steel, oil, sugar, meat, and farm machinery industries. Because the number of corporations was small, owners colluded with one another to create a supply chain that controlled prices and limited competition. These men became known as 'robber barons.' Their power ultimately led to widespread corruption and eventually loss of public trust in a representative democracy.

The loss of public faith in American representative democracy developed during hard economic times. The first post-Civil War depression occurred in the 1870s. During this time, a grasshopper plague devastated farm income in the mid-Western states. Poverty was widespread and communities struggled to survive. Despite the dire economic times, the attitude of railway and eastern promoters toward farmers was 'charge all the traffic can bear' and 'the public be dammed.' In 1893, another economic depression hit, which further contributed to undermining public faith in elected representatives. This time the depression would last 4 years, and unlike the grasshopper plague of the 1870s, most businesses, banks, agricultural interests, and factories were affected. Millions became unemployed and were unable to provide for their families. Criticism of the ruthless practices of the robber barons reached a fever pitch. However, the corporations redoubled their efforts to resist change. Corporate 'thugs' were employed to intimidate and even murder striking workers. Many federal and state governments became 'puppets' of these absentee owners. No wonder that public sentiment turned against absentee owners and elected officials.

Wealth Is Waste: the Rise of Class Consciousness in America

In 1899, Veblen published *The Theory of the Leisure Class*. The study was a critique of economic stratification in postindustrial America. It focused on the outrageous waste of the so-called 'pecuniary culture.' Veblen had first hoped that society would evolve in a peaceable direction; it seemed that the 'instinct of workmanship' guided social development away from social atomism toward the collective good. However, the rise and the new power of business interests of the late nineteenth and early twentieth centuries soon rendered such hopes utopian: social stratification intensified. A new leisure class began to set the standards for desirable goods. Their norms regarding consumption turned out to be the norms to which all other classes aspired. Inexpensive yet functional goods were labeled as 'cheap' and 'unsuitable.' Instead, the consumption of useless goods became a litmus test for social class and status. For Veblen, "so thoroughly has the habit of approving the expensive and disapproving the inexpensive been ingrained into our thinking that we instinctively insist upon at least some measure of wasteful expensiveness in all our consumption, even in the case of goods which are consumed in strict privacy and without the slightest thought of display" (Veblen, 2007: 103f).

Veblen suggested that the privilege of the leisure class had evolved from "primitive savagery to barbarism… from a peaceable to a consistently warlike habit of life" (Veblen, 2007: 11). Class distinctions arose when individuals with desirable traits were rewarded and those with nondesirable traits became subservient to others. Those men rewarded for their warlike traits were held in high esteem; they were imbued with status, power, and leisure time. In modern times, the leisure class included the industrial upper class, athletes, politicians, military officers, and the clergy. For this new class, "time is consumed non-productively from a sense of the unworthiness of productive work, and as an evidence of the pecuniary ability to afford a life of idleness" (Veblen, 2007: 32).

The privileges of the leisure class were similar to those afforded to warriors of primitive cultures. Norms for men in the leisure class were granted permission to engage in behaviors that were taboo for other classes. Men celebrated public drunkenness, the use of stimulants, and promiscuity. Women, whom these men regarded as their property, had to behave along prescribed norms for 'proper ladies.' These men had little care for those women within their social strata, much less for those 'undesirables' on the outside. Women and children as well as other possessions were chattel used to promote the good 'character' of the genteel, well-bred man. Veblen spoke avidly against the crass public demonstrations of waste celebrated by these men and warned against the new conspicuous consumption, which he saw as a return to primitive, barbaric practices.

Critique of Neoclassical Economic Theory

Herbert Spencer's social Darwinism had a major impact on neoclassical economic theory in the Gilded Era. The collusion of a relatively small group of men shaped most decisions regarding governmental regulations on economic activities. As a result, it was not big business that carried the burden of taxation but farmers and other subaltern classes. This, in turn, paved the way for the creation of monopolies that limited competition and distribution of goods and services. Neoclassical economics did not support institutional or governmental interference with market economies because intervention was believed to inhibit market exchanges. According to the theory, it is the individual actor who determines the degree to which wealth is obtained. Those who become wealthy do so by hard work and frugality, while those who are poor are unmotivated or unwilling to work and save.

Veblen was critical of neoclassical economics theory. Veblen viewed economics as an evolutionary science. He offered an alternative hypothesis based on social evolution, accelerated by the spirit of workmanship, and led by peaceable men. His

schema of evolutionary economic growth was influenced by the belief that instincts are not conscious, but are conditioned by and activated through habits. In line with pragmatist reasoning Veblen argued that the nexus of change lies between the individual and macro-social institutions: "every change so made is necessarily made by individuals immersed in the community and exposed to the discipline of group life as it runs in the community, since all life is necessarily group life" (Veblen, 2007: 103f). Accordingly, "social wealth is the stock of human norms, mores and structures of truthfulness" (Veblen, 2007: 173).

Time and again, Veblen critically referred to emulation and predation as a means of creating a real or imagined status based on an outward demonstration of wealth and strength. In contrast to emulation and predation, the instinct of workmanship is an innate drive that seeks to increase productivity and efficiency both for the individual and for the betterment of the community. For example, Veblen used the phrase 'parental bent' to explain altruism, or the tendency to extend one's self to provide for future generations. He also used the term 'idle curiosity' to describe creativity or taking time to think about innovation, as opposed to accepting well-worn 'solutions.' In his day, the colloquialism 'idle hands are the work of the devil' was juxtaposed to his description of 'idle curiosity.'

The Machine Process: Social Rationality in Postindustrial Economies

The corporation, the joint-stock company, and the absentee owner destabilized the relationship between the captain of industry and the community. The working class bore the consequence of the shift. For absentee owners and corporations, there were not any economic incentives for craftsmen to oversee the production of serviceable goods at a reasonable cost. The pecuniary culture supported the production of goods at the lowest cost. Unskilled workers replaced craftsmen, and labor was a commodity bought and sold without concern for societal costs.

In *The Engineers and the Price System*, Veblen argues that the instinct of workmanship will neutralize the predatory instinct of pecuniary culture. Veblen envisioned that workers would eventually evolve to become a force that mediated the influence of business interests (Veblen, 1975). He believed that industrialization would lead to the development of rational worker actors motivated by creative instincts rather than to mindless machine tenders. Industry, as it then existed, was not capable of generating creativity. It was a stifling matter-of-fact condition that reduced workers to parts and pieces of an impersonal assembly line. The machine industry led to 'trained incapacity' or what Dewey described as 'occupational psychosis.' But industrialization could also be a progressive force that would result in an alternative to repetitive work that required little thought or imagination. Innovation would lead to increased efficiency and replace the predatory instincts of business with a community-oriented, creative instinct of workmanship. If inexpensive goods were available to the population, the waste created from conspicuous consumption would lose its appeal and the profitability of the business interests would return to communities as opposed to absentee owners.

Despite such hopes, toward the end of his life Veblen became more and more pessimistic about the promise of evolutionary social change. His hope for the emergence of rational actors, increased innovation, and efficiency gave way to less idealistic observations. As he aged, he was increasingly concerned about the instinct of predatory, coercive barbarism increasing in strength. The engineers who once held promise in Veblen's blueprint for production over profit had now become allies of the class-conscious business interests and distanced themselves from unskilled workers. A hierarchical order of middle-class 'white collar' and lower-class 'blue collar' workers came to be accepted.

The background to Veblen's skepticism lay in World War I, which unified the country through the zeal of patriotism. The post-War years were a celebration of economic prosperity and conspicuous consumption. This was the era of the 'flappers,' a time when new norms for women were recognized. Politicians were bribed and absentee owners were concealed in their feudal kingdoms. At the same time, the upper class became oblivious of the communities it plundered. An economy built on deregulation and nonintervention was breaking under the weight of speculation and unsecured debt. The system was designed for economic growth, not stagnation. For decades, Veblen had warned of the risk of confidence men, who fixed prices and manipulated stock markets, yet few people were listening. Coincidentally, the prophet Veblen died just a few months before his warnings were realized. However, Veblen would have been surprised, first, by the way the Great Depression supplanted conspicuous consumption but also, secondly, by the amount of government regulation of industry that occurred following the Great Depression.

Veblen and "the Academy"

Thorstein Veblen's conflict with the bureaucracy within institutions of higher education may have been established by his early experiences as a student who chaffed against the moral philosophy prescribed by Carleton College or perhaps his status as an outsider in the highly esteemed institutions of his day. Veblen's scholarly works often put him at odds with the 'captains of industry,' who through philanthropy funded many of the academic institutions in which he was employed. Early in his academic career, while still serving the University of Chicago, Veblen had criticized the power of corporations and the impact they had on knowledge production and scholarship. However, his main manifesto, *The Higher Learning in America: A Memorandum on the Conduct of Universities by Business Men*, was not published until 1918.

In it, Veblen criticized the academy for neglecting its moral obligation to the community. He believed that university faculty had a duty to cultivate scientific inquiry. He contrasted the role of the university man with that of the schoolmaster: "The schoolmaster and his work may be equally, or more, valuable to the community at large – presumably more rather than less – but in so far as his chief interest is of the pedagogical sort his place is not in the university" (Veblen, 1965a: 18). Veblen objected to business and political interests giving

vocational colleges the rank of universities. He simply did not believe that the university was a place for schools of law, engineering, teaching, or home economics. He accused universities of adding fields of study that were vocations to "comfort and edify the unlearned with lyceum lectures, to dispense erudition by mail order, and to maintain some putative contact with the amateurs scholars and dilettanti beyond the pale" (Veblen, 1965a: 192).

Business interests supported the development of what Veblen described as 'quasi-universities.' He criticized the appointment of businessmen on university boards. Veblen noted that boards do not "understand or appreciate scholarship or the pursuit of knowledge" (Veblen, 1965a: 142). He criticized those unlearned businessmen who decreased the quality of academic rigor, programs, and personnel. Furthermore, Veblen warned of an academia being compromised by businessmen whose judgments were centered on convenience, as opposed to scientific curiosity. Boards of trustees led by business interests had a negative impact on academia, its programs, and personnel, with scholarship morphing from an 'avocation to that of a vocation.' Veblen warned that "modern learning is of a similarly matter-of-fact, mechanistic complexion, and that it similarly leans on statistically dispassionate tests and formulations…It is the 'dry light of science' that is always in request, and great pain is taken to exclude all color of sentimentality" (Veblen, 1965a: 7). Veblen cautioned that to "the laity a 'university' has come to mean, in the first place and indispensably, an aggregation of buildings and other improved real-estate …. while the pursuit of learning is a relatively obscure matter … the academic work is, after all, unseen" (Veblen, 1965a: 139). He asserted that massive undergraduate training, sports, and amusements, as well as credit for correspondence classes undermined the pursuit of scholarship.

The 'new' universities relaxed academic qualifications and in place of rigor 'student activities' encouraged school spirit. Athletics events were given more attention than scholarly pursuits or the provision of excellent libraries (Veblen, 1965a). In short, Veblen foresaw a time when attendance at universities would become commonplace and vocational training would become the norm, mainly because "men of affairs have taken over the direction of the pursuit of knowledge" (Veblen, 1965a: 77).

Contributions to Modern Sociology and Economics

In his lifetime, Veblen was a highly regarded, albeit misunderstood theorist in sociology and economics. Pragmatism and Darwinism influenced his economic and sociological contributions to both fields of study. His synthesis of pragmatism, Darwinism, and conflict theory continues to influence social scientists today. Veblen's conceptualization of social evolution was unlike any of his predecessors. He considered the effects of economic, social, and cultural changes on how different actors think and act. Veblen wrote that change is "driven by the human instincts of emulation, predation, workmanship, parental bent, and idle curiosity" (Veblen, 1965b).

Veblen viewed social evolution as an illogical process; social evolution was dynamic and unpredictable. However, unforeseen shifts in the social composition of a class, race, or community could create the momentum to change. A new level of functioning could alter how parts related to one another. While Veblen viewed the individual actor as a product of the social system, some powerful individuals could still exert disproportional power on the system. In the late nineteenth and early twentieth centuries, Veblen witnessed these effects and their detrimental consequences, ranging from robber barons and steel magnates to the captains of higher learning.

Veblen's insights about conspicuous consumption, market speculation, and dehumanizing conditions still ring true today. His work serves as a reminder of the risks associated with consumerism, emulation, and predation. Individuals still continue to seek status through the purchase of objects that are, after a short period of time, first discarded and then immediately replaced by new fashionable objects. This cycle is repeated with every new product. Veblen was obviously not fond of marketing and advertisement. For him "falsehood permeates business….As you look out a car window, the rocks and trees are placarded all over with lies … Most advertisements, other than mere announcements for public information, are 'intentional deceptions'" (quoted in Dorfman, 1966: 210).

Contemporary consumerism drives economic growth – and not just in America. Much of the credit crunch of the twenty-first century resembles the economic and political circumstances of Veblen's day. No wonder then that modern economists and sociologists are rediscovering Veblen. The resurgence of interest in Veblen's heterodox economic theories obviously represents an interest in hearing a different point of view, a view that dissents somewhat from standard economics. The fact that Veblen's ideas are still considered worthy of discussion proves that some of his ideas have outlasted those of the more fashionable economic theories of recent times that treated Veblen's ideas and conceptualizations as merely those of a rather eccentric character.

Venture Capital

Martin Kenney, University of California, Davis, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Venture capitalists invest in relatively young, privately owned firms judged to have the potential for fast growth and resultant opportunities to be sold to either the public or existing firms. The first formal venture capital organizations were formed in the United States in the aftermath of World War II. Typically, venture capitalists are actively involved in advising and monitoring their portfolio firms. The dominant organizational form is the venture capital limited partnership, although there are corporations, government entities, and individual investors that also provide venture capital. Today, venture capital as an investment activity is global in scope with approximately 45 nations having some venture capital activity.

Venture capital is a specialized form of investment in relatively young, privately owned firms, judged to have the potential for fast growth. The overriding goal of venture capitalists is to reap outsize capital gains on their original investment within less than 7 years after the investment. This is achieved by selling their stake either through a trade sale or a listing on public stock markets. Venture capitalists are active investors and invariably demand and receive seats on the firm's board of directors from where they monitor their investment and assist management by providing advice, recruiting executives, and participating in important strategic decisions. In the past 50 years, a number of fastest growing US technology firms received funding from venture capitalists. While venture capital as a formal activity first emerged in the United States, in 2012, approximately 45 nations had some venture capital activity (see, for example, Kenney et al., 2008; Guler and Guillen, 2010).

Introduction

The term 'venture capital' was first used in 1939 by Lammot du Pont in Congressional Hearings (Kenney, 2011). Since then, venture capital has evolved into a specialized form of finance supporting small privately owned companies judged to have the potential for fast growth. With few exceptions, the overriding goal of venture capitalists is to reap capital gains in excess of 10 times their original investment in less than 7 years. A most strict definition of venture capital excludes buyouts, loans, and other forms of financial transactions. Venture capitalists invest in equity in the form of common stock, preferred stock, convertible debentures, and/or other financial instruments convertible into common stock when their portfolio company is sold to an acquirer or in a public equity offering. At or shortly after a liquidity event, venture capitalists realize their return as capital gains.

The Venture Capital Industry

Since the 1950s, a number of fast growing US firms, particularly in new technologies, but not confined to them, received venture capital. Examples include Amazon.com, America Online, Amgen, Apple Computer, Cisco Systems, Compaq, DEC, Facebook, Federal Express, Genentech, Google, Intel, Lotus, Netscape, Oracle, Seagate, Sun Microsystems, 3Com, Yahoo!, and countless others. In Europe and Asia, venture capitalists have funded far fewer of these universally known successes; however, there have been some important firms funded including ARM Holdings (UK), Research in Motion (Canada), and Skype (Luxembourg). These firms were central to the establishment of entirely new industries such as biotechnology, semiconductors, software, the Internet, magnetic data storage, a wide variety of computer market segments, and data communications equipment. Today, venture capital is an important institution in the US national system of innovation (Kenney, 2011). In the United States, it has long been known that venture capital investing is and has been regionally concentrated in order of importance in Silicon Valley, Boston, New York, and Southern California (Florida and Kenney, 1988; Sorenson and Stuart, 2001; Chen et al., 2010). Globally, while the United States is by far the largest market for venture capital, significant venture capital markets exist in Canada, China, Israel, Japan, Taiwan, and the United Kingdom (Jeng and Wells, 2000; Megginson, 2004; Wright et al., 2005).

With the formation of the first formal venture capital organization immediately after World War II, there was significant institutional experimentation seeking the best format to support venture investing. Since the late 1950s, there has been a secular increase in the amount of venture capital available, and the number of nations with a venture industry has increased. In 1965, venture capitalists invested less than \$100 million in new ventures, and in 1999, investment peaked at $\$51 \times 10^9$. In 2011, total investment in the United States was $\$28.4 \times 10^9$ (National Venture Capital Association, 2012).

History

For centuries, wealthy individuals have invested in risky ventures in the hopes of securing an outsize return. Such investments can be traced back at least as far as the involvement of merchants in organizing consortia to finance long-distance trading ventures. The financing for firms participating in the Industrial Revolution came from merchants and other wealthy individuals willing to back entrepreneurs building manufacturing facilities or exploiting a new technology. These informal investors are now known

as 'angels,' i.e., individuals who are not professional investors in start-ups (one of the earliest academic articles was Wetzel, 1983).

During the 1930s, in both the United States and the United Kingdom, there were discussions of lack of investment capital for small businesses. In the United Kingdom, the 1931 Macmillan Report identified a shortage of private sector funds for supporting small businesses. The report contributed to a contemporaneous debate in the United States about how to provide funds for the small businesses severely affected by the Great Depression. There was little agreement about what types of small businesses should receive funding and the proper vehicles for providing financing. Prior to World War II, there were a few wealthy families, such as the Mellons, Phipps, Rockefellers, and Whitneys, investing in young ventures. Shortly after World War II, in New York City, these families established offices and hired professional managers to discover, evaluate, and invest in small companies with superior growth prospects. These were the first family venture capital funds. Although each of them changed many of their organizational characteristics, the Rockefeller (Venrock), Whitney (J. H. Whitney), and Phipps (Bessemer Ventures) funds continued to be active in 2000 (Kenney, 2011). The other significant private sector initiative was the establishment of American Research and Development (ARD) in Boston in 1946. ARD was important, not only because of the firms it funded but also because of the Harvard Business School (HBS) faculty member, General Georges Doriot, who established it. Doriot influenced a number of HBS students who later became venture capitalists. As important, Doriot through his writing, speaking, and example defined many of the practices of venture investing. Finally, ARD's $70 000 investment in Digital Equipment Corporation in 1958 was worth $350 million in 1971 – ample proof that significant return was possible (Hsu and Kenney, 2005).

The role of the US government in the development of venture capital has been limited, with a few important exceptions. In 1958, the US government passed legislation creating the Small Business Investment Corporations (SBICs) to encourage investment in small businesses. Despite being plagued by abuse during its first decade, the SBIC program made two important contributions to the development of the industry. The first contribution was its loan guarantees that permitted participants to leverage their private funds. This made low-cost capital available to investors, a number of whom soon left the SBIC program and established important independent venture capital firms. The SBIC Act also loosened Depression-era laws forbidding banks from owning more than 5% equity in any company. By having an SBIC, the banks were permitted to own large equity stakes in their venture-type investments. Particularly in the 1960s and 1970s, banks were a significant source of venture capital. During the 1980s, the limited partnerships displaced them (Kenney, 2011).

There was another federal legislation that had a significant impact on venture capital. The most important was a series of changes in employee pension fund laws during the 1970s. The first change was dramatic tightening by the Employment Retirement Investment Security Act of 1974, which operated to nearly cut off institutional investment in venture capital. The legislation was gradually loosened from 1977 through 1982, and new pension fund monies flooded into the independent firms. The lowering of capital gains tax rates may also have encouraged venture investing (Bygrave and Timmons, 1992; Poterba, 1989; Gompers, 1994). With these important exceptions, the US government has only had a limited role in creating the industry. In other nations, governments have been far more proactive (for example, for East Asia, see Kenney et al. 2002 and Lockett and Wright, 2002; for India, see Dossani and Kenney, 2002; for China, see Ahlstrom et al., 2007; and for Israel, see Avnimelech and Teubal, 2010).

The Venture Capital Limited Partnership

Not surprisingly, the organizational forms for venture capital investing have varied through time. Today, although the independent private venture capital limited partnership is the dominant organizational form globally, it is not the only one. Financial institutions, particularly banks, continue to be active. At times, industrial and other financial corporations have had significant venture capital operations. In the United States and many other nations, subnational government entities such as states or provinces have launched venture capital operations. In some nations, there are also national government-sponsored venture capital organizations. Other organizational formats have included publicly traded closed-end funds, other publicly traded vehicles, and family funds.

By the end of the 1970s in the United States and later in many other nations, the private limited partnership became the dominant format for venture investing. In the limited partnership format, the venture capitalists raise and manage individual partnership funds, each of which is denoted by a Roman numeral in increasing order. The venture capitalists are the general partners, and investors are the limited partners. Investors include pension funds, foundations, endowments, corporations, wealthy individuals, and various other entities. The duration of a particular fund was typically between 7 and 10 years. In the initial 1–3 years the fund actively invests, then in the remaining years it harvests the investments. Successful firms have two or more funds operating simultaneously, each of which is in a different phase of a fund's life cycle.

Compensation for the general partners has two components. The first component is an annual management fee; this can range from 2 to 3% of the limited partner's investment. The fees pay the costs of operating the firm and the salaries of all the employees including the venture capitalists. The other component is the carried interest, which refers to the percentage of the capital gains the venture capitalists retain from the investments after reimbursing the initial investment of the limited partners. The carried interest varies by fund from 20 to 30% of the total returns. After initial investments are returned, the limited partners and general partners receive their prorated share of the capital gains. Returns vary by fund, with certain successful funds having experienced returns in excess of 40% compounded per annum for the life of a specific fund (Metrick and Yasuda, 2010).

Investment Process

Venture capitalists are not passive investors. Because of their equity stake, they have an interest in the firm's success, which is

defined in terms of a rapid increase in the firm's value. Invariably, one or more venture capitalists 'lead investors' join the firm's board of directors. From this position they actively monitor the firm's progress. However, they do more than monitor. They often assist and counsel management. This involvement comes in many forms and is situation dependent, but includes counseling on major strategic decisions, assisting in recruiting key personnel, and providing contacts in the legal, investment banking, and other business service communities. Finally, the investment by a prestigious venture capital firm creates the perception that the small firm will be a success, an important asset for convincing customers and suppliers that the start-up is viable and worthy of patronage.

Entrepreneurship depends on the structure of investment opportunities; in the typical venture capital investment scenario, an entrepreneur or entrepreneurial team approaches a venture capitalist with a business plan describing the firm, the management team, potential competitors, and the market. Since venture capitalists receive hundreds of business plans per annum, those recommended by individuals they know receive the greatest attention. If one or more of the venture capitalists are interested, then the entrepreneurial team is invited to present its business plan in person. Should the venture capitalist's interest continue, a due diligence process is initiated during which the entrepreneurs' references and others who might be able to speak of the candidate's qualifications, personal and technical, are contacted. If there are technological unknowns, the venture capitalist gathers information on the project's feasibility from technical experts. Prospective customers are interviewed to gauge their need or desire for the product. In other words, they gather as much information as possible about the investment and its growth potential. If these hurdles are surmounted, then the team is invited to present the plan to a meeting of all the partners. Should the partners agree, a contract detailing the terms of an offer is extended to the entrepreneurs. Upon acceptance the venture capitalist invests in the firm. With this investment the relationship with the entrepreneur changes, as the venture capitalist now is committed to the success of the firm. Venture capital investments are staged, and, if the firm meets preset milestones, then it receives new investments at a higher valuation. Should the firm not meet its targets or the market changes, at the next stage the firm's valuation can decrease. In some cases, the venture capitalists, if they own more than 50% of the firm and are dissatisfied with the management's performance, will replace the management including, if necessary, the firm's founder(s).

Usually, venture capitalists syndicate their investments with other venture capitalists, thereby spreading risk, providing multiple contacts and sources of advice for the start-up firm, and cross-checking on the investment decision (Gompers and Lerner, 1999). Firms attractive to venture capitalists have the following characteristics. First, the firm is entering a market that is potentially large and promises to grow rapidly. Second, the market will allow rapid scaling, with revenues growing faster than further capital investment. Third, the firm should be capable of increasing rapidly in value allowing a quick payout in terms of capital gains. Some combination of these three characteristics is necessary to ensure that venture capitalists can secure sufficient capital gains on their successes to offset losses on the unsuccessful firms.

There are three outcomes for venture investments: sale of the stock through an initial public offering, sale of the firm to another firm, or bankruptcy. On any of these liquidity events, the proceeds are returned to the limited partners as either cash or marketable securities. As a rule of thumb, three or four investments are expected to fail at a near total loss. Another three or four neither fail nor are easily liquidated. These are termed the 'living dead' and are judged failures by the venture capitalists. It is the final few that have enormous returns that determine a fund's success, compensate for the failures, and complete the venture capital cycle, enabling the venture capitalists to raise a new fund.

The Globalization of Venture Capital

Venture capital as a formal institution was a US innovation. In other countries and other historical periods, merchant banks, governmental bodies, and even family networks performed some similar functions of supporting new entrepreneurs. Beginning in the late 1970s, a few of the US funds looked abroad for funding opportunities and foreign firms began venture investing in the United States; also, in other countries, governments, financial institutions, and individuals wishing to reproduce the US experience established funds targeting local opportunities. Initially, most of these non-US efforts floundered because of a dearth of entrepreneurs; inadequate institutional, financial, and legal infrastructures to nurture and support entrepreneurship; and a lack of experienced venture capitalists. In the late 1990s, due to the opportunities for new firm formation to exploit the Internet, there was a proliferation of venture capital firms, not only in Europe but also in Latin America and Asia. Furthermore, US firms became increasingly active in Asia, most recently in China and India, Europe, and Israel. With the collapse of the Internet bubble many of these failed, but in 2012, most of the Organisation for Economic Co-operation and Development nations have a venture investment community. The most vibrant of these are located in Israel, China, and, to a lesser degree, India (Ernst and Young, 2010). In 2010, China was the second largest market in the world for venture capital investing.

Conclusion

There are continuing debates regarding the efficacy of venture capital-based innovation systems. Today, venture capital is a significant component of the US national innovation system and, while less important in most other nations, it now exists as a source of capital in at least 45 nations. Undoubtedly, governments around the world see venture capital as a socially desirable institution, and nearly all economically significant nations have adopted policies encouraging venture capital formation, although, in most nations, government-established or government-funded venture capitalists have had very limited success. More recently, due to a variety of factors including a lack of high-quality exits, the emergence of extremely large funds, and changing technologies, some industry observers claim that classical venture investing is in decline or being replaced by angel investors. A recent report released by the Kauffman Foundation

has questioned whether the current limited partnership model is the best structure for the investors in venture capital limited partnerships (Mulcahy et al., 2012). As long as there are a significant number of opportunities to create firms capable of extremely rapid growth in value, there will be opportunities for venture investing.

Vestibular System

Abstract

The vestibular system is phylogenetically one of the oldest sensory systems. Its sensory organs detect angular and linear motion of the head relative to space, as well as gravitational forces. The vestibular system generates reflexes in response to head movements to both stabilize the visual axis (gaze) and maintain head and body posture, and is also necessary for our sense of self-motion and orientation in space. In contrast to importance of vision or audition in our daily lives, which can easily be understood by simply shutting our eyes or plugging our ears, the significance of vestibular function is more difficult to appreciate. When the system is functioning normally, we are usually unaware of a distinct sensation arising from vestibular inputs. This is because vestibular signals are integrated with visual, proprioceptive and other sensory information to provide a sense of motion. The critical role played by the vestibular system in everyday life becomes obvious once it has been compromised. For this reason, clinical studies have provided important insights into function of the vestibular system.

Introduction

The vestibular sensory organs, located on the inner ear, are comprised of the (1) two otolithic organs (the saccule and utricle) that sense linear acceleration (i.e., gravity and translational movements) and (2) three semicircular canals that sense angular acceleration in three perpendicular planes. The receptor cells of the otoliths and semicircular canals send signals through the vestibular nerve fibers to the neural structures that control eye movements, posture, and balance, and provide our sense of self-motion (Figure 1). Integration of vestibular information with proprioceptive, motor, visual, and other sensory signals occurs at the earliest stages of sensory processing in the vestibular nuclei and vestibular cerebellum.

When the vestibular system is impaired, normal activities become difficult if not impossible due to gaze instability and the loss of postural control. Fortunately, the brain is capable of substantial recovery after vestibular loss. However, while many symptoms resolve over time as the result of compensatory changes in the vestibular pathway and sensory substitution for the lost vestibular inputs (Sadeghi et al., 2012), recovery is incomplete. In particular, patients often show deficiencies in gaze stability and postural control during activities that include more challenging (i.e., high frequency and velocity) movements.

In recent years, the findings of clinical, behavioral, and neurophysiological studies have led to a better understanding of how the vestibular system functions in normal conditions and after compensation. Below we review some of these findings.

Figure 1 Vestibular signals from the labyrinth of the inner ear are transferred to the vestibular nuclei (VN) via the vestibular afferents of the VIII nerve. In turn, the VN projects to other brain areas to (i) stabilize the visual axis of gaze via the vestibuloocular reflex, (ii) control posture and balance, and (iii) produce estimates of self-motion. VOR, vestibuloocular reflex; VSR, vestibulospinal reflex.

Anatomy of Vestibular End Organs

Movements in three-dimensional space are a combination of rotation and linear movements as well as the omnipresent linear force of gravity. The vestibular end organs, (Figure 2), comprise three semicircular canals (horizontal, posterior vertical, and anterior vertical) that are mutually perpendicular and detect angular motion in all three dimensions of rotation. In addition, each end organ also contains two otolithic organs that detect linear motion: (1) the utricle, which is oriented in the horizontal plane and (2) the saccule, which is oriented in the vertical plane. During everyday activities, our head motion is sensed by the relative movement of the endolymph and the receptor cells within each of these end organs.

The otoliths contain a sensory epithelium called the macula, comprised of hair cells and associated supporting cells (Figure 3). A gelatinous membrane, called the otolithic membrane, overlies the hair cells and their hair bundles also called cilia. Calcium carbonate crystals called otoconia (i.e., Greek for 'ear stones') are embedded in this membrane, and serve to make the membrane heavier than the surrounding

Figure 2 Schematic drawing of the inner ear of man with three semicircular canals, the two otolithic organs and the cochlea.

Figure 3 Schematic of the macula and otolithic membrane in an otolithic organ.

fluid. As a result during linear motion, a relative shearing motion between the otolithic membrane and the macula displaces the hair cell bundles, in turn generating a receptor potential in the hair cells. In particular, the relatively larger mass of the otolithic membrane causes it to lag behind the hair cells of the macula, leading to transient shearing of the hair cell bundle.

The sensory epithelium within each of the three semicircular canals is called the crista and is located in an expansion called the ampulla (**Figure 4**). The cilia of the hair cells of the semicircular canals extend out of the crista into a gelatinous membrane, called the cupula. Importantly, each cupula spans the entire cross section of its ampulla, effectively forming a water-tight barrier through which endolymph cannot flow. Consequently, when the head turns in the plane of one of the semicircular canals, the inertia of the endolymph fluid causes it to lag relative to the hair cells of the crista. Notably, because of the small diameter of the canals (~0.3 mm in humans) and the viscosity of the endolymph, the canals perform a mathematical integration; while the motion stimulus required to activate the canals is rotational head acceleration, the hair cells of the semicircular canals encode rotational head velocity (Chapter 4; Goldberg et al., 2012).

Figure 4 Schematic of the ampulla and cupula of a semicircular duct.

Physiology of the Vestibular System

Vestibular Hair Cells and Afferents

Bending of the cilia of the hair cells opens mechanically gated channels, leading to the inflow of positive ions, and hair cell depolarization. This in turn leads to opening of calcium channels and the calcium-dependent release of neurotransmitters from hair cells onto the afferent nerve terminals. There are two types of vestibular hair cells: type II hair cells which are cylindrical and present in all animals, and flask-shaped type I hair cells that are found only in amniotes (i.e., mammals, reptiles, and birds).

Each type II hair cell is innervated by about 20 bouton afferent terminals that receive inputs from single ribbons. In contrast, each type I hair cell receives a calyx terminal that completely covers its basolateral walls and receives inputs from ~20 ribbons (Lysakowski and Goldberg, 2008). Recent studies have shown that these calyx terminals can receive either synaptic or nonsynaptic inputs from hair cells (Songer and Eatock, 2013) that result in accumulation of potassium ions in the synaptic cleft during stimulation (Contini et al., 2012; Lim et al., 2011). Functionally, afferents can be grouped based on the regularity of their resting discharge, using a normalized coefficient of variation (CV*) (reviewed Goldberg, 2000). Regular units show low variability in interspike intervals (ISI) of resting discharge ($CV^* < 0.1$), while irregular units have higher variability in resting discharge ISI ($CV^* > 0.1$). Afferents with pure bouton terminals that contact type II hair cells have regular discharge properties and mostly innervate the periphery of the vestibular neuroepithelium. In contrast, afferents with pure calyx terminals that contact type I hair cells have irregular discharge and mostly innervate the central area of the neuroepithelium. Most afferents, however, have both bouton and calyx terminals (i.e., dimorphic), and thus contact both type I and II hair cells. These dimorphic afferents can have regular or irregular resting discharge, with regulars and irregulars innervating the peripheral and central areas of the neuroepithelium, respectively. To date, the contribution of boutons versus calyces to the output of dimorphic afferents is not understood.

The responses of semicircular canal afferents with less resting discharge variability (i.e., regular units) encode more information than those with more irregular discharges (Sadeghi et al., 2007). In contrast, more irregular afferents have higher response gains than regular afferents, a difference which increases with increasing frequency (reviewed in Goldberg, 2000). Thus, information from the end organs is sent to the brain via two pathways or information channels: (1) regular afferents which provide more detailed information about the specific trajectory of head motion, and (2) irregular afferents which act as high frequency motion event detectors. Current research is aimed at understanding the functional implications of these differences in coding strategies at higher levels of signal processing (reviewed in Cullen, 2012).

Vestibular Nuclei

The vestibular afferents project to the vestibular nuclear complex which is comprised of four main nuclei: the medial vestibular nucleus (receives inputs mainly from horizontal canals), the superior vestibular nucleus (inputs mainly from vertical canals), the lateral vestibular nucleus (LVN, inputs mainly from saccule), and the inferior (or descending) vestibular nucleus (inputs mainly from utricle and saccule). In addition, vestibular nuclei also receive inputs from other regions of the brainstem, the vestibular cerebellum and higher brain areas (e.g., cortex and cerebellum), relaying extravestibular inputs such as somatosensory, visual, eye movement-related and premotor head movement commands. The

functional implications of this convergence of input at the level of the vestibular nuclei are discussed below in relation to the stabilization and control of gaze (i.e., the vestibuloocular reflex (VOR); Section Stabilization of Gaze by Vestibuloocular Pathways) and posture (i.e., vestibulospinal reflexes; Section Stabilization of Posture by Vestibulospinal Pathway).

Stabilization of Gaze by Vestibuloocular Pathways

As we move through the world, the VOR produces compensatory eye movements equal in magnitude but opposite in direction to head movements to help stabilize the visual world on the retina. These eye movements serve to effectively stabilize gaze and ensure clear vision during our everyday activities. The efficacy of VOR can be easily quantified by measuring eye movements (typically by electrooculography, and more recently by video-based systems) and has thus played a major role in the diagnosis of vestibular disorders. Arguably, the best known clinical case is that of physician who called himself JC. In 1952, JC completely lost all vestibular functions after he was treated with an ototoxic antibiotic (streptomycin) for leg infection. One of his main symptoms was the lack of gaze stability. For instance, he was unable to read street signs or recognize people's faces while walking. However once he stopped moving these images became clear. Notably, for JC as well as other patients with substantial vestibular loss, normal activities that we take for granted become difficult since even small head movements are accompanied by gaze instability since the VOR is no longer effective.

The VOR produces compensatory eye movements in response to both rotational and translational head movements. Specifically, the rotational VOR (r-VOR) is evoked in response to angular head motion that stimulates the semicircular canals (e.g., while shaking head back and forth to indicate the answer 'no'). In contrast, the translational vestibuloocular reflex (t-VOR) is evoked in response to linear head motion that stimulates the otolithic organs (e.g., while riding on a subway or train). In everyday life, rotational and translational head movements generally occur together, and thus the r-VOR and t-VOR are simultaneously evoked.

The neural pathways that mediate the VOR have been well characterized. Additionally, as detailed in the following Chapter entitled *The Vestibulo-ocular Reflex: Adaptation and Compensation* the VOR pathway shows impressive adaptation in response to behavioral requirements. For example, when wearing corrective lens for vision, the VOR adaptively increase or decrease as needed in order to maintain stable gaze during self-motion. In particular, the relative simplicity of the neuronal pathway that mediates the VOR and its calibration has made this reflex an excellent model system for bridging the gap between the cells, neuronal circuits, and behavior. The most direct VOR pathway consists of projections from vestibular afferents to neurons in the vestibular nuclei, which in turn project to extraocular motoneurons, providing eye movements 5–6 m after head movements (Huterer and Cullen, 2002). A schematic showing the pathways mediating the r-VOR evoked by horizontal head movements (i.e., yaw rotations that activate the horizontal semicircular canal) is shown in **Figure 5**. In response to a rightward head motion, the afferents from the right horizontal canals are excited. In turn, these afferents activate central neurons in the vestibular nuclei, which in turn project to the eye muscle motoneurons that drive the movement of both eyes to the left (i.e., the lateral rectus muscle of the left eye and the medial rectus muscle of the right eye). Since the mechanical range of eye rotation is limited anatomically by the extraocular muscle and optical nerve structures, the eye can only move so far to compensate for sustained head motion in any direction. Accordingly, compensatory VOR eye movements are reset by means of a quick phase in the anti-compensatory direction. The inset in **Figure 5** illustrates the eye movements evoked by sustained rightward head rotation. Note the eye movement has a sawtooth pattern, termed 'vestibular nystagmus,' characterized by compensatory 'slow phase' eye movements to the left and rapid resetting 'fast phase' eye movements to the right. The analysis of such vestibular nystagmus is often used clinically to aid in the diagnosis of vestibular disorders.

A similar pattern, known as optokinetic nystagmus, can also be elicited by rotation or translation of the visual field while the person remains stationary. Notably, the optokinetic system uses visual rather than vestibular inputs to stabilize gaze (*see* Visual Streams: Dorsal and Ventral). These eye movements are evoked for example, when a person looks out at the world through a train's window or the side window of a car. In this case the motion of the visual scene causes a compensatory eye movement in the direction opposite to the train's motion with a fast phase in the direction of the train's motion. Importantly, the optokinetic system has response dynamics complementary to those of the VOR. As reviewed above, the VOR has a short latency and is most effective for transient head movements (i.e., >0.1 Hz). In contrast, while the optokinetic system has

Figure 5 Diagram of the reflex pathway generating the vestibuloocular reflex (VOR), showing the response to rightward head motion.

a longer latency, it responds more robustly to low frequency, more sustained head movement where the VOR is less effective. Neurophysiological studies have shown that optokinetic eye movements are largely mediated by subcortical pathways, which project to the second stage of the 3 neuron VOR pathway (see OKN Box in **Figure 5**).

In real world situations, where vestibular and optokinetic stimulation occur simultaneously (as would be the case when walking down the street during the day), commands from the two pathways are integrated within single neurons in the vestibular nuclei to produce sustained responses, that in turn generate robust stabilizing eye movements. In addition, when behaviorally advantageous, it is possible to suppress the VOR. For instance, if we are reading a newspaper when riding as a passenger in a car or bus, our goal is no longer to stabilize the world on the retina. Instead, our goal is to stabilize the words that we are reading – on a page of the newspaper that is moving together with us. In this case, both visual and nonvisual (behaviorally contingent) mechanisms work together to suppress the VOR so that our eyes remain stable relative to the words that are moving with us (rather than relative to the stable world). This mismatch between the vestibular and visual inputs can cause motion sickness if it becomes persistent. In addition, the VOR is suppressed when we make combined eye-head movements to look at targets of interest. Such suppression is useful since the reflexive VOR would drive the eye in the direction opposite to the intended voluntary eye movements made to shift the axis of gaze (*see* Eye Movement, Control of: Oculomotor Control).

As detailed in Section Clinical Manifestations of Vestibular Dysfunction below, spontaneous vestibular nystagmus in the absence of vestibular or visual stimulation is the hallmark of an imbalance of input from the vestibular end organs from the two sides. It is important to eliminate visual fixation in order to fully observe spontaneous nystagmus and in turn diagnose vestibular imbalance. This can be done by having patients wear thick lenses (Frenzel) that prevent them from fixating on visual targets in the local environment.

Stabilization of Posture by Vestibulospinal Pathways

The vestibular system also makes important contributions to the maintenance of posture and control of balance during everyday life. Neurons in the vestibular nuclei that receive direct inputs from the vestibular nerve in turn send direct projections to the spinal tract to control posture and balance. This streamlined circuitry allows the rapid postural corrections in response to unexpected motion vital to prevent falling in normal subjects.

The pathways that control balance have been relatively well characterized. The vestibulospinal tract emerges from the LVN in the brainstem and runs unilaterally to the spinal motoneurons of the extensor muscles (**Figure 6**). When a person experiences rightward motion, the vestibulospinal tract activates the extensor muscles on the right, to counteract the motion that has been experienced. Below we specifically consider the vestibulocollic (VCR) reflex – a vestibulospinal reflex that stabilizes the head in space by activating the neck musculature in response to vestibular stimulation.

Figure 6 Diagram of the reflex pathway generating the vestibulocollic reflex (VCR), showing the response to rightward head motion.

The VCR produces a command to move the head in the direction opposite to that of the current head-in-space motion. Accordingly, it functions to stabilize the head relative to inertial space. Consistent with its role in head stabilization, experiments have shown that the head becomes unstable when the ducts of semicircular canals are blocked to prevent activation of the hair cells during motion. As was the case for the VOR (see Section Stabilization of Gaze by Vestibuloocular Pathways above) the most direct pathway mediating the VCR is comprised of a three-neuron arc. However, in contrast to the VOR, more complicated multisynaptic circuitry makes the dominant contribution to the reflex pathways.

As was the case for the VOR, vestibulospinal reflexes can be counterproductive during certain behaviors. For example, when we make active neck movements the stabilization responses produced by the VCR would produce head-movement commands in the direction opposite to those of the intended self-generated motion. Recent studies have shown that vestibulospinal pathways are suppressed, on average, by about ~70% during the active head movements (reviewed in Cullen, 2012). Interestingly, these same neurons faithfully encode information about passive head rotations, which occur during the execution of voluntary movements. This ability to selectively respond to passive vestibular stimuli during concurrent active and passive motion is likely to underlie our ability to reflexively respond to changes in vestibular input that the brain does not expect. For example, in order to recover from tripping over an obstacle while walking or running, it is crucial that vestibulospinal reflexes generate robust responses to the unexpected component of head motion.

The accurate control of posture and estimation of self-motion further depends on the integration of vestibular and proprioceptive information, which is profoundly disrupted in cerebellar patients. The neuronal computation performed in the cerebellum combines vestibular and proprioceptive information to provide an explicit representation of unexpected motion that ensures accurate spatial orientation and postural control (Brooks and Cullen, 2013). In response to unexpected motion, the cerebellum computes unexpected motion within milliseconds to then send an appropriate signal to the spinal cord to rapidly adjust balance (**Figure 7**). When we move voluntarily, our brain normally construct an estimate of the sensory inflow that it expects from our sensory systems (i.e., vestibular, proprioception, and somatosensory). The cerebellum then computes the mismatch between this expectation and the actual sensory input.

It is thought that athletes can compute this mismatch for very complex motions; consider for example a gymnast doing

Figure 7 Cerebellar nuclei neurons selectively respond to passive head motion when experienced concurrently with active motion.

a back flip on a balance beam. In contrast, cerebellar patients cannot do this, even for a simple movement like placing a foot on a step. In addition, as people age, their sense of balance worsens because they lose some of the sensory input – most notably vestibular input that was present in younger years. As detailed in Section Peripheral Vestibular Disorders below, this makes balance more challenging because there is less reliable information to estimate movements. As a result, older adults often rely more on vision, which is a relatively slow sense compared with vestibular and proprioceptive systems. Rehabilitation programs often encourage patients to retrain their sensory organization and use faster sensory inputs such as vestibular and proprioception to improve their balance.

Interestingly, the sensation of height vertigo has also been explained within the context of sensory mismatch. This sensation occurs when a person stands on the top of a high tower or the edge of a cliff. While standing, most people display some degree of body sway that is regulated by the multisensory convergence in the vestibular system. In this particular context, vision plays a major role. Notably there is a discrepancy in visual perception of motion as a result of the difference in distance between the background – located far from the foreground. The lack of consistent information impairs postural control and thus increases body sway potentially operating in a 'positive feedback' loop. Instability can be counteracted having the subject focus their view on the near foreground, or by providing other stabilizing sensory cues – for example, by allowing him or her to hold on to a hand rail or touch the ground.

Multisensory Integration during Self-Motion in Everyday Life

As reviewed above, information from the vestibular sensors is combined with extravestibular cues, such as proprioception, visual inputs and motor efference signals, at the earliest stages of central vestibular processing. As a result, the multimodal representations of self-motion are used to provide: (1) Behaviorally appropriate gating of reflexes including the VOR and VCR during active shifts of gaze and active head movements, respectively; (2) Estimates of the relative motion of neighboring parts of the body (e.g., body vs head motion) required to ensure stable posture and perception; and (3) Accurate representations of unexpected self motion required for perceptional stability. This integration is also evident at higher levels of vestibular processing. Notably, the convergence of visual, proprioceptive, and vestibular inputs is observed in the main vestibular cortical area, the parietoinsular vestibular cortex (PIVC) as well as in head direction neurons (found in the lateral mammillary nuclei, retrosplenial cortex, lateral dorsal thalamus, striatum, and entorhinal cortex) that discharge in relation to the animal's directional heading with respect to the environment.

Clinical Manifestations of Vestibular Dysfunction

Disorders of the vestibular system are more difficult to identify than those of other sensory systems (i.e., hearing loss or blindness in the case of the auditory and visual systems). Nevertheless, the symptoms of vestibular dysfunction namely, dizziness, imbalance, and disequilibrium are extremely common. The probability of vestibular dysfunction increases with age. For example, a recent epidemiological study (National Health and Nutrition Examination Surveys (NHANES)) suggests that 35% of adults in the United States aged 40 and older have vestibular dysfunction, corresponding to nearly 70 million Americans.

The most common peripheral vestibular disorders include: (1) Benign paroxysmal positional vertigo (BPPV) in which patients have the false sense of self-rotation when adopting certain static head positions, (2) Ménière's disease in which patients experience episodes of vertigo, fluctuating hearing loss, and tinnitus (illusionary ringing in the ears), (3) sudden unilateral peripheral vestibular loss, and (4) superior semicircular canal dehiscence syndrome, which leads to symptoms and signs of vestibular and auditory dysfunction. Each of these disorders can cause gaze instability and postural imbalance and in addition often have complex psychological manifestations (including anxiety and phobias). Finally, it is important to mention that the loss of peripheral vestibular input with aging plays a prominent role in the cause of falls in the elderly. Below, we consider the physiological cause of each disorder as well as current treatments used to ameliorate deficits. Comprehensive

descriptions of central disorders (e.g., migraine-associated dizziness, vertebrobasilar ischemic stroke, and vertebrobasilar insufficiency) can be found elsewhere (Dieterich, 2007).

Peripheral Vestibular Disorders

Benign paroxysmal positional vertigo (BPPN) is the most common cause of vertigo, experienced by more than 50% of people over the age of 70. BPPN occurs when dislodged calcium carbonate crystals from the otoconial membrane of the utricle move into a semicircular canal duct. Typically, due to the geometry of the labyrinth, dislodged crystals accumulate in the posterior semicircular canal. Accordingly, the resultant nystagmus is most often comprised of vertical and torsional eye movement. The dynamics of the crystals motion through the labyrinth endolymph account for the long latency of the pathological nystagmus (typically 10–15 s after the head movement). To treat BPPV, the patient's head is moved to position the plane of the affected posterior canal vertically. In turn, this causes the crystals to move from the canal duct into the crus commune and then into the vestibule as a result of gravity, from where they are subsequently absorbed.

Ménière's disease is characterized by periods of vertigo, hearing loss, and tinnitus and results in a substantial reduction in quality of life. Episodes of vertigo, especially their unpredictability, often prevent Ménière's disease-afflicted patients from conducting daily activities and can create anxiety. Historically, the underlying cause was thought to be related to an excess of fluid in the inner ear called 'hydrops.' However, the disease probably has multiple etiologies including viral and autoimmune responses, hereditary predisposition, and head injuries.

Sudden unilateral loss of peripheral function is most commonly caused by vestibular neuritis which is thought to be of either a viral or vascular origin. The resulting inflammation and possible ischemic injury to hair cells and/or afferent nerve fibers leads to a loss of peripheral function in the affected side. In addition, surgery for acoustic neuromas produces unilateral loss of vestibular function. More rapid onset of the loss of vestibular function produces more severe symptoms of gaze instability and postural instability. Patients also commonly experience a sense of severe rotatory vertigo which can be accompanied by nausea and vomiting.

Immediately, following vestibular loss, patients will have a spontaneous nystagmus, that includes horizontal and torsional components (with slow phases of the nystagmus directed toward the affected side). Furthermore, the unilateral loss of otolithic function produces an ocular tilt reaction characterized by a counter-rolling of the eyes toward the side of vestibular hypofunction when the head is tilted in the roll axis. Finally, and most important clinically, a patient's horizontal VOR becomes asymmetric, such that head rotations that would have excited the horizontal canal on the damaged side (and inhibit canals on the intact side) generate a very small angular VOR.

In most patients, many of these symptoms resolve within a week, however gaze stability remains subpar for the more challenging head rotations. The functional improvement observed is the result of compensatory processes in central vestibular pathways, as well as the substitution of information from the proprioceptive, visual and motor systems (Sadeghi et al., 2012). Interestingly, the degree to which compensation and substitution strategies are helpful varies considerably across patients. Common rehabilitation procedures such as Cawthorne-Cooksey exercises effectively incorporate multimodal (i.e., combined vestibular and proprioceptive) stimulation into rehabilitative training to promote compensation.

Superior semicircular canal dehiscence syndrome is a relatively rare disorder. It is caused by a thinning or opening in the bone overlying the superior semicircular canal. Symptoms include autophony (the sensation that one's voice is too loud in the affected ear), sound-induced loss of balance (Tullio phenomenon), and low frequency hearing loss. The cause is thought to be either congenital or the result of physical trauma to the head. Treatment is usually surgical resurfacing/replacing of the affected bone.

Vestibular Function and Aging

Numerous studies provide evidence for age-related changes in peripheral vestibular sensory organs. In particular, aging is accompanied by progressive hair cell degeneration, otoconial degeneration in the otolithic organs, and decreasing number of Scarpa's ganglion neurons. Type II hair cell counts decline at the same rate for all 5 sensory epithelia. Type I hair cell counts decrease in all three semicircular canals at a significantly faster rate than in the otoliths. There is also a decrease in primary vestibular neurons. As a result, the efficacy of the VOR decreases with age and older adults also become more susceptible to falls and dizziness.

Abstract

Motor learning not only allows us to develop the skills necessary to perform fine-tuned movements, such as a tennis serve, but also ensures the accuracy of simpler reflex behaviors. Notably, the vestibulo-ocular reflex (VOR), which functions to stabilize images on the retina, shows impressive adaptation in response to changes in environment requirements, such as those imposed by a new pair of eyeglasses. The pathways that mediate the VOR and its adaptation are relatively simple, making this reflex an excellent model system for bridging the gap between brain and behavior. This article reviews behavioral, electrophysiological, and lesion studies of VOR adaptation.

Introduction to Vestibulo-Ocular Reflex

As reviewed in the previous article entitled *The Vestibular System*, the vestibulo-ocular reflex (VOR) produces eye movements that are equal in magnitude but opposite in direction to the head motion in order to stabilize gaze over a wide range of head movements. For example, when a subject experiences rightward head rotation in darkness, the VOR will produce an eye motion to the left. The gain of the rotational VOR, defined as compensatory eye velocity divided by head velocity, is ~1.0. The three-neuron arc that is responsible for mediating the direct VOR pathway consists of projections from vestibular afferents to interneurons in the vestibular nuclei, which in turn project to extraocular motoneurons (**Figure 1(a)**). The simplicity of this pathway is reflected in its fast response time (**Figure 1(b)**): compensatory eye movements lag head movements by only 5–6 ms in the primate (reviewed in Cullen, 2012). Because, the VOR initiates eye movements at much shorter latencies than visually mediated eye movements and is thus fast enough to stabilize the gaze during common activities such as locomotion.

Within the vestibular nuclei, the primary interneurons that mediate the direct VOR pathway are called position-vestibular-pause (PVP) neurons (**Figure 1(a)**; reviewed in Cullen, 2012), named so because in addition to responding to vestibular stimulation, they encode eye position signals and pause during saccades. A second class of interneurons, termed floccular target neurons (FTNs), also contribute to the VOR pathway (**Figure 1(a)**; reviewed in Cullen, 2012). Notably, FTNs receive input from the flocculus of the cerebellum as well as from the vestibular nerve. The responses of FTNs complement those of PVP neurons during our daily activities, and play a vital role in calibrating the VOR (reviewed in the following section).

Adaptive Capability of the VOR

A mismatch between visual and vestibular stimuli drives VOR adaptation. A typical training paradigm used to induce changes in the VOR gain is illustrated in **Figure 2**. Before any training, the VOR gain is approximately unity, so that, the eyes move with the same amplitude, but in the opposite direction, as the head. A decrease in VOR gain is induced by training with visual motion in the same direction as the head (gain-down stimulus). Following this type of training, the magnitude of the eye movement is less than that of the head and the VOR gain is reduced (<1). An increase in VOR gain occurs when visual motion is in the direction opposite to the head (gain-up

Figure 1 (a) Circuit diagram describing pathways that mediate the VOR. The direct pathway mediating the VOR consists of vestibular afferents, which project to the primary VOR interneurons in the vestibular nuclei, which in turn project to ocular motoneurons. Secondary VOR interneurons receive input from the vestibular afferents and the cerebellar flocculus, and also project to ocular motoneurons. These cells are part of the pathway that is involved in the calibration of the VOR. (b) Eye response following a transient head perturbation. Following the onset of head rotation, the eye begins to counter-rotate after a latency of 5–6 ms. The gain of the reflex is eye velocity divided by head velocity. Note: eye velocity has been inverted to facilitate comparison. Modified from Huterer and Cullen (2002).

Figure 2 A typical training paradigm used to induce changes in the VOR gain. Before any training, the VOR gain is ~1, that is the eyes move with the same amplitude, but in the opposite direction from the head. A decrease in VOR gain is induced by training with image motion in the same direction as the head (gain-down stimulus). Following this type of training the magnitude of the eye movement is less than that of the head and the VOR gain is reduced (<1). An increase in VOR gain occurs when image motion is in the direction opposite that of the head (gain-up stimulus). Subsequently, the magnitude of the eye movement is more than that of the head and the VOR gain is increased (>1).

stimulus). Subsequently, the magnitude of the eye movement is more than that of the head and the VOR gain is increased (>1).

One of the most impressive examples of VOR adaptation was shown by Gonshor and Jones (1976). In this study, participants wore optical lenses that induced vision-reversal such that left was right and vice versa. The gain of the VOR immediately dropped within 2 days of wearing lenses. After 3–4 weeks the response of the VOR actually reversed: VOR eye movements moved in the same direction of the head. Therefore, VOR was able to adapt to these dramatic new conditions resulting from the change in optics so that gaze stability could be achieved. While in everyday life the demands on the VOR are less challenging, VOR adaption is nevertheless essential to ensure gaze stability. In humans, during the first few years of life, the VOR is continuously adjusted to account for large changes in the size of the head (head circumference increases by 30% in the first year). Later in life, the VOR adapts to account for the magnification of corrective lenses when prescribed, such as for myopia. For example, individuals suffering from myopia are typically prescribed convex corrective lenses resulting in their VOR gains being lower than people who do not wear glasses. During aging, the reflex is also able to adapt to the incremental loss of the receptor cells. Finally, the VOR shows remarkable recovery following the loss of unilateral labyrinthine input as a result of injury.

Cerebellar Flocculus

The floccular complex is a structure within the cerebellum and is required for VOR motor learning; the gain of the VOR cannot be adapted after this structure has been removed. In primates, the flocculus proper is defined as the four most medial lobules caudal to the posterolateral fissure. Adjacent to the fissure is a lobule that constitutes a transition zone, termed the medial extension, which is then followed by five to six more rostral lobules that make up the ventral paraflocculus. Like all of the cerebellum, the flocculus receives two main types of inputs: (1) mossy fibers and (2) climbing fibers (Figure 3(a)). Mossy fiber inputs provide head movement-related information (i.e., vestibular) via projections from the vestibular nerve and vestibular nuclei as well as eye movement-related information from the vestibular, reticular, raphe, and perihypoglossal nuclei. The mossy fibers project to granule cells, whose axons form the parallel fibers. These parallel fibers make synapses onto the dense dendrites of Purkinje cells, which, in turn, project to FTNs in the vestibular nuclei. The climbing fiber input originates in the inferior olive and makes strong synaptic connections onto Purkinje cells. Although typically only one climbing fiber will project to a single Purkinje cell, the strength of the synapse is powerful enough to evoke repetitive discharge in that Purkinje cell. This inhibitory side loop through the cerebellar flocculus (Figure 3(a)) plays an important role in mediating VOR adaptation (reviewed in the following section).

The mossy fibers and climbing fibers influence the discharge pattern of Purkinje cells differently. Mossy fiber input will give rise to simple spikes (Figure 3(b)) in Purkinje cell firing, which can reach discharge rates as large as 300 sp/s. On other hand, climbing fiber input causes complex spikes in Purkinje cells (Figure 3(b)), which occur less often than simple spikes (at a rate of ~1 sp/s) and are longer in duration than simple spikes, lasting for as long as 2–5 ms.

Two Influential Models of Learning in the VOR

In order to change the gain of the VOR response, synaptic weights within the pathway that mediates this reflex must be

Figure 3 (a) Two pathways control the gain of the VOR. The main reflex path with a gain α is paralleled by an inhibitory side branch through the floccular complex of the cerebellum with a gain β, so that total gain is proportional to (α–β). *Abbreviations:* CF, climbing fibers; GC, granule cells; MF, mossy fibers; OMN, oculomotor nuclei; Pc, Purkinje cells. (b) Recordings from an example Purkinje cell showing its high-frequency simple spike responses as well as a complex response modulated by a climbing fiber. Climbing fiber excitation results in an EPSP followed by a pause in firing rate. Courtesy of Simpson, J., and Maruta, J.

altered. Where and how these adaptive processes occur has been debated, and two hypotheses of motor learning in the VOR have dominated the literature (reviewed in Broussard and Kassardjian, 2004). The principal difference between these two models is the location of the modified synapses that underlie VOR adaptation.

In 1972, Ito proposed a theory of VOR adaptation based on the Marr–Albus model of cerebellar motor learning. In Ito's framework, the climbing fibers from the inferior olive send retinal slip or an error signal to the floccular Purkinje cells. This generates complex spikes, which triggers a change in the weight of the synapse between the parallel fibers and the Purkinje cells. This error signal modifies the head velocity-related modulation of Purkinje cells in order to change the gain of this cerebellar loop of the VOR circuitry so that the VOR is compensatory (Figure 4(a); red star).

On the other hand, Miles and Lisberger proposed that the projection from floccular Purkinje cells to neurons in the vestibular nuclei induced learning, causing plasticity exclusively within the brainstem (Figure 4(b); green star). This hypothesis proposes that during normal VOR, the eye and head movement inputs effectively cancel out and floccular Purkinje cells are not modulated. When there is a visual–vestibular mismatch, however, retinal slip would drive smooth pursuit eye movements in order to maintain stable gaze. This eye movement signal would get sent to Purkinje cells, whose output would encode the error between the eye and head movement. Finally, the error signal guides plastic changes at the level of neurons in the vestibular nuclei, so that the modified VOR pathways will produce stable gaze.

Evidence for a Multisite Hypothesis of VOR Motor Learning

More recent evidence from single unit recording experiments indicates that the site of VOR motor learning is not exclusively restricted to the floccular complex or the vestibular nuclei (reviewed in Broussard and Kassardjian, 2004). During

Figure 4 Two classic models of VOR motor leaning. (a) In Ito's model, climbing fibers encode a visual error signal which induces learning at the synapses of parallel fibers onto the Purkinje cells. (b) In the Miles–Lisberger model, floccular Purkinje cells encode an error signal which induces the modification of synapses onto target neurons in the vestibular nuclei. *Abbreviations:* CF, climbing fibers; GC, granule cells; MF, mossy fibers; OMN, oculomotor nuclei; Pc, Purkinje cells.

conditions that induce VOR motor learning, changes in the simple and complex spike activity of Purkinje cells are appropriate to drive these adaptive changes providing evidence for Ito's proposal of VOR motor learning. However, once a new VOR gain state has been established, the responses of FTNs in the vestibular nuclei are also modified.

The results of lesion studies have furthered the proposal that the site of VOR motor learning is not restricted to either the floccular complex or the vestibular nuclei. Specifically, changes in VOR gain are completely abolished by inactivation of the floccular complex immediately following learning, while inactivation of the floccular complex does not completely abolish long-term changes in VOR gain. Taken together, recording and lesion studies provide strong evidence that the gain changes required for VOR adaptation are initially stored in the floccular complex, and drive the formation of long-term synaptic modifications at the level of the vestibular nuclei such that long-term memory is chiefly consolidated in the brainstem rather than the cerebellum. This process has been termed the transfer or consolidation hypothesis (reviewed in Broussard and Kassardjian, 2004).

Cellular Mechanisms for VOR Motor Learning

As described above, there is general agreement that the synaptic plasticity required for VOR adaptation first occurs in the floccular complex, and the Purkinje cell response in turn drives the formation of long-term synaptic changes at the level of the vestibular nuclei. Much work has been devoted to investigating the cellular mechanisms of these synaptic changes in the floccular complex and vestibular nuclei. As is reviewed in articles "Long-term potentiation; Long-term depression," the two forms of synaptic plasticity are long-term depression (LTD) and long-term potentiation (LTP), which lead to a decrease and increase, respectively, in synaptic efficacy.

It has long been known that LTD occurs at the parallel fiber to Purkinje cell synapse when the climbing fibers and parallel fibers are simultaneously stimulated. More recent work has furthered this providing insight into the role of LTD in VOR adaptation (reviewed in Cullen, 2008). For example, blocking cerebellar LTD pharmacologically impairs VOR adaptation. In addition, transgenic mice expressing an inhibitor of protein kinase C, a molecular required for cerebellar LTD, exhibit impairments of VOR adaptation. There have also been reports on the importance of cerebellar LTP in VOR adaptation. Blocking the T-type channel, required for cerebellar LTP, in mice impaired VOR adaptation (Ly et al., 2013). Taken together, these studies suggest that both cerebellar LTD and LTP play a role during VOR motor learning.

Recently, *in vitro* studies have provided insight into the cellular mechanisms that mediate synaptic plasticity at the level of the vestibular nuclei. It has been shown that repetitive stimulation of the vestibular nerve can evoke LTD at the afferent-vestibular nuclei neuron synapse when paired with postsynaptic depolarization or LTP when paired with postsynaptic hyperpolarization (McElvain et al., 2010). LTP appears to depend on AMPA receptors whereas LTD requires NMDA receptors. Another complementary study has shown that either LTD or LTP can be evoked at the afferent-vestibular nuclei neuron synapse using repetitive stimulation of vestibular afferents depending on the pattern of pulse trains that are being delivered (Scarduzio et al., 2012). Short durations between pulse trains lead to LTP whereas long durations results in LTD. These results show that synaptic plasticity can occur within the vestibular nuclei and suggest that these changes, alongside synaptic modifications within the cerebellum reviewed above, likely play a role in guiding VOR motor learning.

VOR Adaptation and Treatment Options for Vestibular Disorders

Under normal conditions the VOR is effective (i.e., gain of unity) over the full range of head movements, which can easily reach accelerations and velocities of up to 25 000 deg s^{-2} and 500 deg s^{-1}, respectively. Immediately following unilateral lesion, however, VOR responses are

Figure 5 Changes in the axis of VOR eye movements induced with the vestibular prosthesis for a monkey over the course of 7 days of wearing the device. Each data vector depicts the axis and magnitude of VOR responses during sinusoidal rotations about the horizontal canal axis, and rotations in axes that stimulate the right anterior canal with the left posterior canal (RALP), and the left anterior canal with the right posterior canal (LARP) in push–pull pairs. Vector length indicates the peak response velocity and the direction of the vector indicates the axis of the VOR eye movements; for comparison, thick axes without markers depict ideal responses (i.e., VOR gain of 1). Modified from Dai, C., Fridman, G.Y., Chiang, B., Rahman, M.A., Ahn, J.H., Davidovics, N.S., Della Santina, C.C., 2013 Directional plasticity rapidly improves 3D vestibulo-ocular reflex alignment in monkeys using a multichannel vestibular prosthesis. Journal of the Association for Research in Otolaryngology 14, 863–877.

decreased, and patients experience gaze instability and accompanying vertigo. Fortunately, most patients exhibit remarkable recovery within 1 week for sinusoidal rotations with low frequencies and velocities (reviewed in Cullen et al., 2009). Yet, in response to more challenging stimuli (e.g., rapid rotations of up to 500 deg s^{-1}), compensation is not complete and VOR responses are asymmetric (VOR gains are ~0.7 and 0.3 for contralesional and ipsilesional-directed rotations, respectively).

As mentioned above, patients suffering from vestibular deficiency typically exhibit a unilateral vestibular hypofunction and exhibit asymmetric VOR responses. Therefore, training that would lead to increases in VOR responses during both ipsilesional and contralesional directed rotations would not be beneficial for these patients. One recent study has shown that the VOR is capable of unilateral adaptation (Migliaccio and Schubert, 2013). Following a unilateral VOR adaptation paradigm, researchers found that VOR gains toward the adapted side increased when tested during passively applied head movements, whereas VOR gains toward the non-adapted side did not. Clinicians can take advantage of these results to further the development of vestibular rehabilitation exercises.

Vestibular patients with bilateral loss of function suffer from debilitating symptoms for which there remain no adequate treatment options. Ongoing research is focused on developing a chronically implanted vestibular prosthesis as a treatment option for these patients. This device consists of a gyroscope, which senses the movement of the head and transmits this signal to electrode arrays implanted in each semicircular canal, which stimulate the vestibular nerve and sends this information to the rest of the brain. The vestibular prosthetic stimulation, like natural stimulation, can produce both reflexive eye and head movements (Mitchell et al., 2013). Furthermore, animals rendered bilaterally vestibular deficient and implanted with a prosthesis achieve partial restoration of the VOR responses, which improve when the device is worn for extended periods of time (Lewis et al., 2010). Finally, the misalignment of the VOR eye movement relative to the axis being stimulated decreases over the course of 1 week (**Figure 5**; Dai et al., 2013). The ability of the VOR neural circuitry to adapt to stimulation delivered by a vestibular prosthesis is promising for patients in need of treatment to relieve symptoms associated with bilateral vestibular deficiency.

Victimless Crime

Steven Block, Central Connecticut State University, New Britain, CT, USA

Abstract

Victimless crimes are difficult to define and categorize, but they unarguably account for considerable attention and resources in legal discussion and criminal justice system processing. Crimes commonly labeled victimless include drug use, gambling, prostitution, pornography, adultery, and sodomy. These behaviors are normally legislated on one or more grounds: harm to others, offense to others, harm to self, or a violation of morals. Yet, critics suggest that society would benefit from decriminalization or legalization.

Most criminal acts involve identifiable victims who directly suffer as a result of the crime. In contrast, victimless crimes have no direct victims and are often the subject of intense public policy discussion. Drug use, gambling, prostitution, and pornography are among actions that are traditionally classified in this category (Veneziano and Veneziano, 1993). Whether other behaviors, such as driving an automobile under the influence of alcohol, committing tax fraud, and illegally possessing a firearm, are victimless crimes is debated. Although the word 'victimless' is rarely used in legal settings, the term is more commonly utilized to illuminate the debate about the role of government in this set of activities.

Definitions of victimless crime have been formulated since the 1960s. Packer (1968) described victimless crimes as "offenses that do not result in anyone's feeling that he has been injured so as to impel him to bring the offense to the attention of the authorities" (p.151). Similarly, Morris and Hawkins (1970) state that "these crimes lack victims in the sense of complainants asking for the protection of the criminal law" (p. 6). Earlier, Schur (1965) wrote that the term "refers essentially to the willing exchange, among adults, of strongly demanded, but legally proscribed goods or services" (p. 169). Other words are also used to describe similar, if not identical, groups of behaviors including vice (Skolnick, 1998), consensual (McWilliams, 1996), public order, and fringe crimes (Clement and Barbrey, 2008).

While there are few themes that connect all victimless crimes, many concepts separate the majority of victimless crimes from other groups of criminal behavior, such as personal violent and property crimes. Foremost, as indicated in the proposed definitions, victimless crimes are actions that do not have clearly identifiable victims. Violent, property, and white-collar crimes normally have victims who are likely to feel as their direct interests have been harmed, but victimless crimes contain only secondary victims or no victims at all.

Analyses of drug use, gambling, prostitution, and pornography involve questions about both harmfulness and morality. Each behavior has the potential to harm the actor and indirectly harm other people. Harms may be physical, financial, or psychological. Further, several victimless crimes also violate standards of morality for certain populations. Although morality is most often linked to sexual behavior, ethical and religious concerns are also raised about personal drug use and gambling. Morality is rarely discussed for other victimless crimes that relate to strictly personal safety, such as motor vehicle violations or jaywalking.

Another unique characteristic of victimless crime that separates this category from other offenses is the controversial legal status. Nearly all organized societies prohibit *mala in se* crimes such as sexual assault, robbery, and theft. Conversely, there is great division over the legal statuses of *mala prohibita* victimless crimes. This subjectivity is well represented by considering a historical account of laws against victimless crimes. Most countries have experienced time periods when laws have shifted for drug use, gambling, and prostitution.

A last theme of victimless crimes is that they are generally viewed by the public as being less serious than other forms of crime. Multiple studies have constructed rankings of crime seriousness ranging back to criminological research in the 1960s and 1970s. Consistently, various types of violence and property offenses are ranked as more serious than victimless crimes by respondents using different sample populations (Cullen et al., 1982; Rossi et al., 1974).

Justifications for Legislation

The philosophical debate about the role of law in private behavior began with John Stuart Mill's 'On Liberty' written in 1859. Mill assisted in creating the fundamental position of liberalism when he posited that the only justification for infringing on a citizen's individual liberties is when the interests of others are directly harmed. Mill's core arguments were eventually challenged by James Fitzjames Stephen who believed that society maintains the right to enforce laws, apart from harming others, under particular circumstances. The Mill–Stephen conflict laid the framework for two diverging viewpoints. The release of the United Kingdom's Wolfenden Report on prostitution and homosexuality in the 1950s reinvigorated the academic discussion about the role of harm and morality in law nearly a century after Stephen's response to Mill. Consequently, Lord Patrick Devlin and H.L.A. Hart engaged in debate about the proper scope of criminal law. Hart extended and clarified Mill's points in creating the idea of legal positivism, which challenged that any relationship should exist between law and morality. Devlin, echoing the words of Stephen, claimed that society's future relied upon a shared set of values. Further, he questioned whether a lack of morality would result in any less impact than acts violating loyalty toward a nation. Years later, Joel Feinberg (1984, 1985, 1986, 1988) produced

an authoritative four-volume series that meticulously outlined the four main justifications for criminal law. Although this philosophical debate persists today, legal scholars claim that the importance of morality has diminished with arguments from both liberal and conservative perspectives now considering whether specific acts involve enough harm to justify legislation (Harcourt, 1999). Research has shown that justifications for legal intervention toward victimless crimes, related to harm and morality, are also reflected in citizen opinions (Stylianou, 2010).

Harm to Others

Mill's sole justification for creating limitations on personal freedom was the harm principle. There is virtual consensus that if an act harms other people directly, this may be a justifiable reason for creating laws. However, several complex challenges emerge in the application of the harm principle. First, there are several forms of harm that go beyond physical ramifications. Other examples of harm include financial and emotional impact. A compulsive gambler might commit acts of violence to fund a habit, cause family bankruptcy with reckless wagering, and create tense relationships within the household. While all of these results are considered harmful, there is no agreement upon which forms of harm justify legal intervention. Second, it is uncertain whether harm must be a definite result caused by an action to be considered within this category of 'harm to others.' When an intoxicated driver violates drunk-driving laws, he or she increases the risk of harm for other individuals, but the actor does not always cause actual harm to other individuals. In most cases, no one suffers harm from this infraction, yet it is agreed that driving while intoxicated increases the likelihood that harm will occur.

Offense to Others

Some actions offend others in society without causing direct harm to their interests. Joel Feinberg (1985) expressed the idea that people other than the actor may be affected by an action without directly harming them. Victimless crime laws targeting public nudity and obscenity are more closely related to offensiveness than harmfulness. Several other offenses are viewed as a public nuisance, which, in many cases, serves as grounds for legal action. Yet, offensiveness is subjective, which leads to difficulties in determining which activities are offensive enough to warrant legal intervention. The behaviors that offend one individual do not necessarily correlate with the offenses that will offend other members of society.

Legal Paternalism

Beyond affecting other people and their interests, victimless crimes often impact the offender themselves. Although there may be indirect harm toward other people, laws requiring the use of motorcycle helmets and motor vehicle seatbelts chiefly protect individuals from harming themselves. Legal paternalism assumes that the government possesses the ability to make better decisions than individuals who may be swayed by emotion, excitement, and poor analytical skills. Feinberg (1986) divides paternalism into two categories: soft paternalism and hard paternalism. Soft paternalists, like Feinberg, argue that it is justifiable to make paternalistic laws when an individual makes a decision that is not entirely voluntary. Hard paternalists suggest that the protection of an individual alone, voluntary or not, is a sufficient reason to create a law. Critics of enforcing laws based on paternalistic grounds argue that individuals should have the right to engage in risky behaviors as long as it only harms their own interests. Further, several self-harming behaviors such as eating unhealthy foods, sun tanning, and climbing mountains are rarely considered for criminal legislation. One important complication to analyzing the paternalism doctrine is the perspective that acts that harm an actor do indirectly impact the lives of others in some manner. For instance, a drug habit influences family members emotionally, as well as the overall productivity of society, therefore harming all persons in that society indirectly.

Legal Moralism

Apart from harm, the legal moralism doctrine supposes that acts may be outlawed to enforce a consensus morality that exists within a society. This rationale for prohibiting victimless acts is perhaps the most controversial and was the primary concentration of the Mill–Stephen and Hart–Devlin debates. Questions of morality commonly focus on sexual acts such as sodomy, fornication, and adultery. Critics of legal moralism doubt whether it is just to use law to evaluate the moral systems of individuals. Further, in many instances no moral consensus emerges. In practice, the enforcement of morality often reflects the moral standards of persons in positions of power rather than all citizens within a society. The moral beliefs of minority populations are likely to be diminished and persecuted through law under legal moralism.

Perspectives on Victimless Crimes

Several unique political and social perspectives provide insight about the variety of approaches for handling victimless crimes. Beyond the fundamental liberal and conservative viewpoints, ideological perspectives on victimless acts include the libertarian movement, harm reduction, the 'broken windows' approach, and feminism. Libertarians support less governmental intrusion in private lives. Accordingly, the libertarian perspective on victimless crimes pushes for a minimization of criminal laws. In addition, libertarians do not support governments taking control of markets, but rather they support open markets that allow for individuals to exercise their own freedoms.

Another perspective on victimless crime is the harm reduction movement. Harm reductionists accept that people will engage in potentially risky activity and rejects 'zero tolerance' attitudes. Harm reductionists support systems that apply a public health approach that allows for treatment rather than criminal justice approaches that rely mainly on punishment. Additionally, education and awareness focuses on producing accurate information about safe engagement in these activities. Harm reduction supporters claim that zero tolerance approaches depend upon exaggeration and intimidation to deter participation.

Based on the assumption that community disorder leads to more serious criminality, the 'broken windows' perspective promotes strict enforcement of laws against quality of life offenses that occur in public and will portray a community in a negative manner (Kelling and Wilson, 1982). Several victimless crimes contribute to community disorder including street prostitution, obscenity, panhandling, graffiti, and jaywalking. Some cities in the United States, including New York City, used the 'broken windows' approach to change policing tactics during the 1990s. Critics of the 'broken windows' logic and implementation question whether there is an overuse of criminal justice resources. Others suggest that problematic activities are simply displaced to other settings when enforced in particular areas.

Many victimless crimes involve women or the portrayal of women. The feminist movement has been particularly vocal about prostitution and pornography. One branch of feminism supports tougher, stricter laws toward prostitution and pornography with a focus on eliminating them from society. Proponents of this viewpoint typically argue that gender roles are reinforced and that there is rarely a truly voluntary act that takes place. Rather, these feminists believe that coercion and abuse are rampant within any system of prostitution and pornography. Oppositely, another segment of feminism views sex work within prostitution and pornography as empowering. This side of the argument argues that when women act as the supply within the sex trade, they perform legitimate work that is in demand with a great amount of control that is rarely available in other industries for women.

Arguments for and against Prohibition

Proponents of legal restrictions for victimless crimes rely upon several separate arguments. Most centrally, an important logical assumption is that unwanted behaviors can be reduced or eliminated through prohibition. For some people, this reduction in the behavior is caused by a fear of legal repercussions. Other people may abstain from the behavior due to a respect for the role of law. Examples of declining cocaine and opium use following the Harrison Narcotics Act of 1914 and lower levels of alcohol use during and after alcohol prohibition in the 1920s and 1930s are examples of this success in the United States. The prohibition of a disapproved act also demonstrates total governmental condemnation of a particular behavior irrespective of whether the prevalence of the act declines.

The alleged connection between victimless crimes and other forms of predatory crime provides further justification for legal intervention for prohibitionists. Some victimless crimes possess a clear relation with secondary forms of crime. Prohibition supporters commonly rely on a causal link between the act in question and violence or property crimes. Suggested relationships include cocaine, amphetamines, and alcohol with violence (Parker and Auerhahn, 1998), sex work with physical and sexual assaults (Farley, 2004), gambling with income-generating crimes (Stitt et al., 2003), and pornography with forcible rape (Malamuth et al., 2000).

Even in cases where there is no apparent link with secondary harms, most victimless crimes are considered to be unproductive, because the behavior is recreational. Several drugs that lack a clear connection with serious crime, such as marijuana, are condemned for creating more apathetic users. Similarly, gambling is often critiqued as an exchange of money with no tangible, productive outcome for society.

A separate argument proposed by prohibitionists relates to accessibility for youth. Both prohibitionists and legalization supporters typically agree that children should not have access to participating in victimless acts. When policies are developed short of full prohibition, completely reducing access to children is unlikely. Most countries set a particular age at which young adults are permitted to use alcohol. Yet, these age-graded restrictions do not stop youth from accessing alcohol. Efforts also are enacted to reduce access to pornography, gambling establishments, and registered firearms, although full prohibition is argued to be the most aggressive approach for limiting access to youth.

The movement to remove criminal sanctions for victimless crimes also produces several multidimensional arguments. Some of these perspectives are based on the philosophical role of law in society, while others are formed around practical concerns. Foremost, it is suggested that creating legal restrictions for acts that do not directly harm other individuals is an undue infringement upon individual freedoms. These sentiments are rooted in the writings of John Stuart Mill and other liberal thinkers. In some countries, arguments are made that restrictions on personal freedoms violate constitutional protections, such as the 9th and 14th Amendments in the United States.

Labeling theorists suggest that interactions with the criminal justice system create an unnecessary stigma associated with being labeled a criminal or deviant. These labels have both a formal and informal impact on the offender and their ability to function within society. Because criminals face these difficulties, there is an increased likelihood that they will commit more serious crimes. Persons supporting decriminalization and legalization often believe that the removal of criminal sanctions for minor offenses will reduce further criminality by eliminating these labels.

Another argument in support of legalization is the difficulty associated with preventing citizens from engaging in private behaviors. In the case of drugs, like alcohol and tobacco, millions of users worldwide are addicted to these substances and prohibition alone does not address their addiction. Legislation that changes a behavior's status from being legal to illegal must also consider the ramifications of addiction and compulsion.

A related issue is the cost and difficulty associated with enforcing criminal laws. If victimless crime laws are enforced, offenders will be arrested, processed, and incarcerated which costs money to taxpayers. Based on the assumption that there is no complaining victim, law enforcement must resort to aggressive techniques including using paid informants, listening to wiretaps, searching suspect vehicles, and conducting potentially risky sting operations. These approaches are often time-consuming and dangerous. Proponents of legalization believe that these valuable police, court, and corrections system resources should be shifted toward more serious crimes with identifiable victims. In a recent year, over 500 000 prisoners were incarcerated in the United States alone for drug and public order offenses, according to the

Bureau of Justice Statistics (Carson and Sabol, 2011). The maintenance of these prisoners is expensive and most do not contribute productively to the workforce while incarcerated.

When crimes without victims are enforced, enticing opportunities for corruption emerge for criminal justice system practitioners. Critics suggest that a major downfall of alcohol prohibition in the United States was the corruption of persons responsible for enforcement. Without the lack of a complaining victim, police or other individuals in the justice system are presented with opportunities for bribery that do not exist with other offenses. Another related problem is selective policing and prosecution. Victimless crime enforcement allows for targeting of populations based on class, race, gender, age, or personal vendetta.

Legalization supporters suggest that illegal markets will develop when a prohibited commodity or good is in demand. Because participants in illegal markets do not have protection from the justice system and the ability to sue when there are disagreements or misunderstandings, violence ensues. In the country of Bhutan, lawmakers banned the sale of tobacco in 2004, but an illegal market reportedly emerged, as did violence during alcohol prohibition in the United States in the 1920s. In the case of drug violence, critics of victimless crime laws claim that violence associated with increasing income to purchase prohibited goods (economic compulsive) and violence related to illegal markets (systemic) could both be greatly reduced, if not eliminated, with legalization. In addition to promoting violence, illegal markets allow for individuals and organized crime to gain financial proceeds from illicit activity, while restricting governmental tax revenue.

The removal of criminal sanctions provides governments with the ability to control several aspects of a particular act. Where applicable, governments can tax, regulate use, and monitor use and distribution in ways that are not possible under a prohibition system. In the Netherlands, the creation of red light districts permits authorities to restrict the sale of sexual services to a specific area within cities. In the US state of Nevada, prostitution is often zoned to secluded areas where sex workers operate under strict regulations. The control of prostitution also results in lower levels of violence (Brents and Hausbeck, 2005). Additionally, the use of excise taxes, another form of control, has been shown to limit alcohol and drug consumption (Cook, 2008). Under a criminalization scheme, these forms of governmental control disappear.

Several scholars have weighed the arguments of both sides of the legalization debate and concluded that a more complex legal solution is needed beyond simple prohibition or legalization. One sociologist proposes creating a dualistic prostitution legal system that legalizes and controls indoor prostitution while outlawing street prostitution and enforcing such laws (Weitzer, 1999). Meanwhile, others have suggested that drug policies should rely on licensing and exclusion as a more moderate approach to prohibition (Leitzel, 2013).

Approaches to Reducing Victimless Crime

Strategies to reduce victimless crime normally focus on either the supply or demand associated with the illegal markets. Supply reduction techniques target the supply of drugs, prostitution, gambling rings, and pornography. Critics of supply reduction claim that such policies tend to be expensive and intrusive. Further, supply markets for drugs and prostitution rebuild and reconfigure even following significant interventions. In the case of drug trafficking organizations, arrests of drug carriers create opportunities for others to become involved in the trade. Likewise, consumers may switch drug allegiances or shift from street prostitution to indoor prostitution when supply markets are changed. Common controversial techniques targeting illicit markets include the eradication of drug-producing crops, civil forfeiture of assets, the creation of increased penalty zones, and various covert operations.

Other approaches focus on directly reducing the demand within illegal markets. These techniques include forms of prevention, punishment, and treatment. Both educational and awareness programs are commonly instituted to minimize drug use, prostitution, gambling, and other similar acts. Educational programs often involve schools or community programs to deliver messages, while awareness programs utilize several outlets including the media. Punishments toward the demand side, include, but are not limited to, criminal sanctions (e.g., probation, incarceration, fines) and formal restrictions on access to public services and voting rights. Under the category of treatment, rehabilitative techniques, such as peer-based 12-step programs and individual professional counseling, attempt to change established behavior.

Other policies reflect the harm reduction movement. Harm reduction focuses on limiting the actual harm that results from acts of drug use, gambling, and prostitution rather than solely attempting to eradicate the problem. The harm reduction movement is criticized for accepting and promoting negative behaviors, yet proponents cite evidence of lower sexually transmitted disease rates in prostitution and overdose levels for serious drug use when harm reduction policies are applied. In Switzerland, voters in 2008 approved the continuation of a pilot program to prescribe heroin to perpetually addicted users. According to one study, the measure positively impacted illicit heroin markets and reduced criminal activity associated with the illegal drug trade in the country (Killias and Aebi, 2000). Most innovative harm reduction initiatives are in Western European nations or Canada and public support for the movement appears strongest in these countries, as well.

The Future of Victimless Crime

Controversy about the role of government in private behavior has lasted for centuries. The first strong, organized movement to outlaw several victimless acts took place in the late nineteenth century. In the United States, state and federal laws were passed restricting personal drug use, prostitution and sex trafficking, and forms of gambling such as the lottery. Through the twentieth century, many laws against drugs, prostitution, and gambling were maintained or strengthened. By the 1960s and 1970s, a decriminalization movement occurred in the US grounded in a changing population and belief that prohibition caused more problems than it solved. Several drugs were decriminalized in individual states. Accordingly, state lotteries emerged, the presence of large casinos spread, and

pornography became more regulated in the US and across the world. Many other countries have similarly experienced a liberalization of several victimless crimes throughout the twentieth century.

Recent legal changes indicate that the shift toward a liberal philosophy continues around the world. Portugal became one of the first developed countries to decriminalize drug possession in 2001, instituting a system in which users were referred to treatment, opposed to traditional criminal prosecution. After a decade, these changes appeared to have positive effects on overall usage rates and accessibility to treatment (Greenwald, 2009). Other countries have followed the Portuguese model. The Argentinian Supreme Court ruled that laws prohibiting personal consumption of marijuana to be unconstitutional, because the state lacked the power to enforce morals. During elections in November of 2012, voters in Colorado and Washington in the US approved legalization measures for marijuana. These states became the first to legalize recreational marijuana use, although many others have approved marijuana use for medicinal purposes.

Prostitution approaches have also become more progressive in several countries. In many Western European nations, including Germany, the Netherlands, and Hungary, prostitution is now legalized and controlled. In Hungary, for instance, sex workers pay taxes and maintain appropriate documentation for their work. In Sweden, a 1999 law removed criminal laws targeting sex workers while maintaining the ability to arrest and prosecute consumers. Within the next decade, Norway and Iceland followed the Swedish model to decriminalize the sale of sex.

Drastic changes in victimless crime policy have also impacted gambling. Since the 1980s, casinos in the United States have expanded from two locations in Las Vegas, Nevada and Atlantic City, New Jersey to more than 35 states today. Government-sanctioned lotteries exist in many industrialized countries, including the United States and United Kingdom. Further, the progression of Internet-based gambling has increased the challenges associated with enforcing regulations and prohibitions.

Liberalization has also impacted laws that are rarely prosecuted. In a 2003 landmark US Supreme Court decision, *Lawrence v. Texas*, the Court majority ruled that laws prohibiting consensual sodomy were unconstitutional. Lower courts have applied the *Lawrence* finding to cases involving other consensual sex acts. Other countries have repealed laws against sodomy or had challenges to laws prohibiting nonreproductive sex. Early in the twenty-first century, many jurisdictions legalized assisted suicide, as well.

Despite this apparent shift in favor of liberalism, other changes to victimless crime laws have become more restrictive. In the US state of Rhode Island, lawmakers recriminalized indoor prostitution in 2009. Drug laws targeting several newer substances vary by state in the US with many states moving to criminalize drugs that are viewed as emerging problems. Further, international treaties bind nations together, which presents a challenge for countries considering legalizing particular drugs. Based on historical considerations and contemporary viewpoints, debates about the proper level of intervention for victimless crimes are likely to continue in the future as they have for more than 150 years across the world.

Video Cultures: Television

Abstract

The sociological study of television has not kept pace with the new media environments that have developed from emerging digital-interactive technologies. As a result, sociology's theoretical approaches to understanding the cultures of television production, distribution, and consumption lag in their ability to account for the transformations that have taken place. To address this gap we discuss foundational work and recent developments on topics that are central to the study of television – media technologies and social life, audiences, production, and globalization. For each, we draw upon research from the fields of communication and media that are relevant to sociological concerns alongside scholarship by sociologists to understand the video cultures of contemporary television.

Introduction

Television was introduced as an experimental technology in the 1920s and 1930s in Europe, Asia, the former Soviet Union, and the Americas, and following the Second World War it rapidly became a widely accepted form of mass communication around the globe under a variety of national regulatory arrangements. Among early postwar adopters were France, who kept the production, distribution and broadcasting of television programs as a state monopoly in 1945; England, as a subsidized public service in 1946; the United States, as a commercial medium in 1948; Canada, as national system in 1952; Japan, in 1953; as dual public and commercial networks; and Australia, as a free and governmentally regulated broadcast service in 1956. Although television's long-term business cycle – its innovation and diffusion as a novel technology, establishment and system growth as a communications industry, maturation and popularity, and specialization and diversification – took decades to unfold (Cunningham, 2000), its widespread adoption as an important source of news, information, and entertainment quickly led to a multifaceted approach to its study. Initially, scholarly analysis focused on television in several definitive ways – as a cultural form, an industry, a technology, and as a medium shaped by national policy – and this eventually expanded to encompass its study as a global influence and its audience(s). Early attention by social scientists, especially among those in the United states, brought focus to this comprehensive vision by paying particular attention to television's social impact (see, for example, Bogart, 1956). (Bogart (1956) covered television's history, appeal, content, and consumption, effect on other media, relationship with advertisers, and influence on politics and youth.)

However, as Grindstaff and Turow (2006) have observed, since the 1950s, sociology's dominant conceptual approaches to the study of television have fallen short in two key ways. One is their inability to account for video cultures – the new media environments that develop from the "continually emerging sets of multifaceted digital-interactive technologies" (p. 103) – that have grown around contemporary television's production, distribution, and consumption. The other is the inadequacy of sociology's theoretical approaches to the study of television – the political economy perspective that largely attends to issues of power at a macrolevel along with how ownership and control of television and the organization of television production practices shape and influence content, and the cultural perspective that focuses more on the expressive and symbolic dimensions of television programming and reception – to keep up with the industry's transformation. As Grindstaff and Turow (2006) observe, "contemporary changes in the medium threaten to make past research on television appear quaint and anachronistic" (p. 103), but this theoretical lag should challenge scholars to find ways "to draw from enduring perspectives from the older work and assess how they apply to the new-media environment" (p. 103).

In this article we consider the issues raised by Grindstaff and Turow's (2006) thoughtful assessment of television sociology. We agree that there is a need to update existing theoretical approaches for capturing television's newer formulations, especially television's more extensive global presence on the one hand and its deeper penetration of everyday social life on the other. Over two decades ago, media scholar George Gerbner (1993) observed that "Mass media, particularly television, form the common mainstream of contemporary culture. They present a steady, repetitive, and compelling system of images. For the first time in human history, most of the stories are told to most of the children not by their parents, their schools, or their church but by a group of distant corporations with something to sell" (p. 207). This was echoed nearly a decade later when leading media sociologist Todd Gitlin stated that "the obvious but hard-to-grasp truth is that living with the media is today one of the main things Americans and many other human beings do" (2001: p. 5). More recently, this fact was underscored when leading communications scholar Sonia Livingstone challenged colleagues, in her 2008 presidential address to the International Communication Association, to more thoughtfully probe how "the media mediate everything, entering into and shaping the mundane yet significant relations among individuals and between individuals and society" (2009: p. xi). (In posing this challenge, Livingstone drew the distinction between mediation, "in which the mass media comprise one of many influential but independent institutions whose relations with the media can be usefully analyzed" and mediatization, which implies that "that all influential institutions in

society have themselves been transformed, reconstituted by contemporary processes of mediation" (2009: p. 2). While mediatization – the subordination of important social institutions to the media – remains an open question, mediation does not.) In short, with media now so unquestionably ubiquitous and so widely recognized as permeating every facet of social life, sociology is at a crucial juncture if it is to remain relevant as a contributor to the study of media in general and to the field of television, in particular.

To this end, we discuss foundational work and recent developments on topics that are central to the study of television – media technologies and social life, audiences, production, and globalization. For each, we draw upon research from the fields of communication and media that are relevant to sociological concerns alongside scholarship by sociologists to understand the video cultures of today's television.

Media Technologies and Social Life

Television's initial cultural setting was the household. Although there is scattered early ethnographic work about its presence in extensions of the domestic sphere such as taverns, hotels, and hospitals (e.g., May, 1999), television's 'ambience' was more thoroughly conceptualized when Anna McCarthy (2001) examined the personal uses of television in public spaces that included airports, train stations, retail outlets, and the like, outside the home. McCarthy's research enabled scholars to focus comparatively on the ways in which the medium interacted with its setting, and how that interplay shaped its use by viewers. McCarthy's conceptualization built upon the important scholarship by Lynn Spigel (1992) on television's contribution to the evolution of the post–Second World War (WWII) domestic sphere. Spigel's (1992) work demonstrated how the public's adoption of television as a domestic medium was influenced not just by the quest for audiences by large corporations, but also and equally importantly by the subjective responses to the technology by housewives of the 1950s whose then-prescribed social responsibility as homemakers made them gatekeepers of that domain. It was the response of housewives who ultimately shaped not only television's acceptability as a presence in the domestic realm, but equally importantly its cultural form, because in order for family gatekeepers to find the medium acceptable, its content had to be seen as relatable. (The marketing of the Princess telephone by Bell Telephone (Lupton, 1993) and of the cell phone by Nokia (Djelic and Ainamo, 2005) are other examples of how technological innovation, in order to become widely adopted, had to be subordinated to the cultural expectations of potential users before they could become instruments of sociable interaction.)

A consequence of the research on television's early adoption spawned the important line of scholarship on audiences, which we discuss below. However, it is first necessary to address the significance of how recent new technologies of distribution that include the secondary marketing of series on digital video disk (DVD) (and in the older physical format of videotape), TV subscription outlets like video-on-demand (VOD) and pay-per-view, and streaming over the Internet through other so-called over the top electronic services such as Netflix and Hulu have transformed access to the medium and are creating new forms of consumption. These forms of *a la carte* access were presciently anticipated by W. Russell Neuman in *The Future of the Mass Audience* (1991), in which he wrote of the future fragmentation of the mass audience and its fallout, niche programming. This (r)evolution in access is highly socially significant because it has implications for how we organize as a society around access, including as voluntary communities of like-minded individuals who share interests and tastes; how we conduct ourselves in public spaces, such as the workplace, that integrate the leisure/entertainment/information content that television offers; how consumption of the traditional serialized narrative structure of television has evolved into 'binge' or 'marathon' viewing wherein the watching of a series becomes like consuming a novel and allows for greater scrutiny of aesthetic quality (Chmielewski, 2013; McNamara, 2012); and the prevalence of so-called social TV that consists of real-time conversations happening online while viewing (Jurgensen, 2013). According to Jenkins (2006), these developments have so profoundly transformed the processes of media consumption that they have given rise to a "convergence culture" between media users and producers that has enhanced the extent to which audiences eagerly anticipate and avidly participate in developments in media narratives (Leaver, 2013; Milner, 2009). At the crux of this cultural shift is the development of what Jenkins calls a "transmedia impulse" for storytelling (2006: p. 133), a narrative "universe" that arises when audiences trace and combine plots that unfold across multiple media distribution formats (books, movies, comic books, games, and fan-generated knowledge and content). (Fans have always relied upon secondary and tertiary texts to supplement their reading of primary texts (see Fiske, 1987), and they have created a robust industry out of fan fiction (Alter, 2012), but Jenkins (2006: p. 98) argues that convergence culture relies upon collective intelligence on the part of the consumer and the audience to read an entertainment franchise or brand (i.e., a narrative universe) horizontally across formats and platforms. While Fiske's textual layers and Jenkins's convergence culture are clear adjuncts to the primary text that are partly audience-generated, Gray's (2008) concept of paratext regards promos, trailers, advertising, and the like as overt attempts by the industry to direct audience expectations of the primary text.)

Transformations in media consumption like these will continue to evolve, and they are readily sociologically contextualized. It is well known that marketers target consumers on age-based demographic characteristics, and while 18- to 49-year-olds are the single most important consumer market post–WWII (Turow, 1997), the child/youth ('tween') market has become equally important (because broadcast networks and advertisers seek to establish an early relationship with consumers), especially as an indicator of the adoption of new media technologies. Although the transformations in television consumption described above and the emergence of other online use patterns are presently more prevalent among online teens, GenY, GenX, and Younger Boomers relative to older age groups (Turow, 2011: p. 494), as the range of distribution technologies becomes more accessible, simplified, and understandable, consumption practices will eventually change for everyone. That said, recent statistics suggest that traditional

broadcast television will be around for some time to come. (Due to space limitations we are unable to address the growing 'posttelevision' scholarly literature which examines the future of traditional broadcast television in a world of convergence culture; see, for example, Spigel and Olsson (2004) and Lotz (2013).) Recent Nielsen data indicate that "teens consume the vast, vast majority of their video content via traditional television" (Juenger, quoted in Flint, 2013: p. B1), despite their ready adoption of new media formats and technologies. Finally, the introduction and adoption of new distribution technologies and transformation of consumption practices indicate there is still much for sociologists to learn about the impact of the social uses of these technologies on society and in everyday life. Cultural differences reflected by chronological age are often presumed (see Freese et al., 2006, for example), but recent analysis suggests chronological age is less relevant to the ways in which viewers relate to television content (Harrington and Bielby, 2010; Harrington et al., 2011). Finally, large questions still remain about the societal implications of the Internet, which is the genesis of this revolution. These include the relationship of the digital divide to inequality, the extent to which the Internet furthers social isolation or social capital and community formation, its beneficial or detrimental impact on politics, its impact on bureaucratic structure and worker control, and its potentially diversifying, hyper-segmenting, or massifying effect on societal culture (political elections and terrorism being equally compelling if diametrically opposed uses) (DiMaggio et al., 2001).

Audiences

The audience is crucial to the existence of television, not only as a market that creates demand for the shows advertisers subsidize through commercials, but also as the locus of interpretative activity that contributes to making the content of television programs culturally significant. As an industry, television is in the business of creating and selling programs, but from the industry's standpoint its real business is the creating and selling of audiences – as consumers who will buy what they see advertised, and as commodities to be marketed to advertisers who sponsor the shows. Interpretative activity is shaped by the audience's social activities and cultural identities as it seeks out and consumes particular programs. These two views of the relevance of the audience to television have created separate lines of scholarship from different disciplinary perspectives and only recently, through the study of fandom, are they in potential dialog with one other.

The measurement of the television audience that the industry relies upon to understand its market grew directly out of measurement techniques used in radio; these included the systematic measurement of audience size that yielded information about a potential market, and the measurement of program ratings that indexed a show's popularity (see, for example, Lasswell, 1948; Lazarsfeld, 1940). Because the concept of reaching the largest possible audience of potential consumers is pivotal to the success of commercial television, early research by sociologists on audiences focused on the concept of the mass audience, the broad reach that advertisers desired and that networks needed to establish themselves. Although then-influential scholarly work of the Frankfurt School aligned the notion of the mass audience with a vulnerability to persuasion by powerful social institutions, others challenged the presumptive notion of the audience as a mass of indistinguishable individuals, groups, or categories (Lang, 1957; Rosenberg and White, 1957) (Subsequent research has revealed how audience segmentation (e.g., social status, gender, age, employment, religion, and political affiliation) is associated with media use (Roe, 2000; van Eijck and van Rees, 2000; van Rees and van Eijck, 2003).), and still others who directly studied media effects challenged the presumption of persuasiveness, arguing that "media content was filtered by interpersonal networks, by individual need, and by selectivity in exposure and perception" (Katz, 1977: p. 22).

Issues of measurement precision have always been a matter of ongoing discussion between the industry and ratings companies, the leading one being A.C. Nielsen, because advertisers rely upon the accuracy of ratings data to determine advertising rates and where best to place their sponsorship. Recent innovations by Nielsen to the measurement of TV viewership to better capture the impact of new digital technology upon audience engagement include joining with Twitter, Inc., which is the leader in real-time television engagement, to create a new, separate industry metric "that will gauge penetration based entirely on data from the popular microblogging website and social network" (O'Connell, 2012). Another modification is Nielsen's decision to expand beyond the traditional TV definition of television by introducing a comprehensive plan to capture all video viewing including broadband, Xbox, and iPads (Block, 2013). A still unresolved debate between the networks and Nielsen is the networks' push for advertisers to pay for live ratings plus online and digital video recorder (DVR) viewing within 7 days, as opposed to the live ratings plus 3 days they pay for now (Bond, 2013). (DVRs, which are present in nearly half of all homes with a television, are primarily used to record scripted fare, not sports programming or awards shows. The television industry would like to see DVRs phased out and video-on-demand (VOD) become the predominant alternative viewing platform because VOD does not allow commercials to be skipped (Flint, 2012).) In short, viewers' use of digital technologies has changed the very definition of the practical ways in which audiences construct their viewership, and this has, in turn, transformed not only the commodification of the audience but also traditional dynamics between the industries of advertising, marketing, and television.

The study of fandom has opened up intriguing avenues of study for television scholars that align the characteristics of audiences with aspects of their engagement. Two decades ago, the study of *Star Trek* fans by Henry Jenkins (1992) and Camille Bacon-Smith (1992), and of soap opera fans by Harrington and Bielby (1995a), launched the first wave of fandom studies, the study of fans' interpretative communities. These foundational works, along with Joli Jensen's (1992) penetrating insights into cultural assumptions about fans in general, established the importance of studying fan cultures in order to understand the social legitimacy, meaning, and significance of intensive viewing practices. The wealth of research produced in the second wave of fandom studies documented how fandom is integrated with modern life (see Gray et al., 2007), and yet a great deal of work

remains to be done on fans' individual motivations, enjoyment, and pleasures, which comprise the third wave of scholarship on fandom. This entails, in particular, "furthering our understanding of how we form emotional bonds with ourselves and others in a modern, mediated world" through fan communities (2007: p. 10). (For example, new media technologies have transformed how fans record encounters with a celebrity. Fans' insistence on taking a photo of oneself with a famous person has all but replaced the standard artifact of the autograph (Villarreal, 2013). In another example, as ever more people spend more of their lives online, social media sites are now, also, becoming a public space for the conduct of traditional cultural rituals such as mourning the death and preserving the memory of beloved cultural figures (Khatchatourian, 2013).) Very recent scholarship on fandom's contribution to the social bonds that comprise everyday life, how individuals utilize fandom as a resource for navigating the boundaries of ascribed sociodemographic categories such as age, gender, race, and social origins, and even fandom's role in rewriting of the institutional structure, organization, and dynamics of the life course offer rich insight into the ever-deepening embeddedness of media institutions like television in the lives of individuals in the twenty-first century (Gatson and Reid, 2011; Harrington and Bielby, 2010; Harrington et al., 2011; Harrington and Brothers, 2010). However, as some have already noted, fandoms, whether they are virtual or face-to-face, are still stratified communities with cliques, hierarchies, and conflict (Pearson, 2010) and associated power dynamics (Harrington and Bielby, 1995b), as is the case in all societies.

Production

Guided by the production of culture perspective (Peterson and Anand, 2004), the sociological study of television as a system of industrial organization has yielded considerable insight into how television, as a culture industry, fabricates expressive-symbolic elements. In conjunction with the concepts of the art world (Becker, 1982), the culture world (Crane, 1992), and the fiction complex (Griswold, 2000), the production of culture perspective captures the organizational complexity of the television industry and its myriad institutional participants, such as policy makers who determine availability of content or products from other sources, professional critics who appraise product quality, and audiences whose taste preferences influence producers and shape product trends. Early work influenced by the production of culture approach focused primarily on elaborating the structure and dynamics of television's industrial systems per se (see, for example, Muriel Cantor's 1971 study of the television producer and Intintoli's 1984 ethnography of the production of soap operas). However, over time, scholars incorporated analysis of other pivotal aspects of the industry such as industry boundary spanners and gatekeepers who serve as intermediaries that link the industry's loosely coupled components, target innovation, and move products along (Hirsch, 1972), and industry executives' use of symbolic or ritualistic practices to manage the extreme uncertainty, risk, and ambiguity in audience preferences (Bielby and Bielby, 1994). As a whole, this body of work reveals that television strives to be a highly rationalized industry, but does not necessarily succeed at this goal.

The disconnect between the industry's rationalized aspects and its extreme business uncertainty opened the door to research on how the distinctive features of creative industries like television shape the subjective work experience of its employees. Important work by Hesmondhalgh (2007) (Hesmondhalgh and Baker, 2011) reveals that there is a chasm between scholars who celebrate creative jobs in the technology-driven economy, where there is flexibility, safety, autonomy, intrinsic satisfaction, name recognition, and the integration of conception and execution, and those who recognize that knowledge economy jobs are also marked by high levels of insecurity, casualization, and long working hours that result in self-exploitation. Research on localized production cultures among industry workers has specifically targeted the individual-level sense-making that creative workers undertake as they labor (Caldwell, 2008). Questions about sense-making become particularly relevant when studying workers who use information and communication technologies that allow the labor of production to be, on the one hand, dispersed across geographic locations, and, on the other, 'virtually' close transnational collaborations. How is collaboration enacted? How are artistic conventions understood? A recent line of scholarly work focuses on the analysis of change in television formats and production in the 'postnetwork' (i.e., mass/broadcast) era of multichannel, multiplatform television (Lotz, 2007), and its effect on traditional television formats such as the talk show (unchanged due to its segmented format that satisfies Internet-affected taste for 'video snacks') and the nightly news (in decline because of competition from on-demand availability of news around the clock). It remains to be seen how the study of localized production cultures in particular and the production of culture more generally will be affected as distinct lines of inquiry and as scholarly paradigms by the developments of the postnetwork era, in particular, as the demand for new job skills arises and established ones die out, whether a postbroadcast era will continue to translate into a wider range of desirable program options (pay cable networks have already vastly enhanced the content, artiness, and quality of serialized dramas(McNamara, 2013)), what the textual attributes and features of newer program options might be, and how this broadening of program options will affect the industry's labor market, and access to it, for talent behind the camera as well as in front (Ross, 2011).

Television's Globalization

Why has sociology lagged as an equal contributor to the analysis of these industry developments? In this section we discuss one last development in the television industry, its globalization. (Use of the term globalization here is in the sociological sense of the increasing interconnectedness of different parts of the world. Our use here refers specifically to cultural globalization, which Crane (2002: p. 1) defines as "the transmission or diffusion across national borders of various forms of media and the arts." See also Giddens (1990). We recognize the debates among globalization scholars about the adequacy of their own conceptualizations of culture and

globalization (see Bielby, 2010).) With few exceptions (Cantor and Cantor, 1986; Havens, 2006; Bielby and Harrington, 2008), not only has this topic received limited attention by sociologists, it reveals in precise ways where concerted theoretical work is needed in order for sociology to keep abreast with the industry's transformation.

The study of the global market for television was launched by the now-classic United Nations Educational, Scientific and Cultural Organization (UNESCO) study by Nordenstreng and Varis (1974), which provided one of the earliest attempts to systematically document the export of television programming. Their work uncovered a 'one-way flow' of television content from the United States, Britain, France, and the Federal Republic of Germany to the rest of the world, with the United States leading this group. Although their statistics revealed that a large number of hours of airtime were exported, it is now well understood that importing was deployed for a limited time by nations in the process of building their own emerging national television systems, and that as a strategy this proved to be far more cost effective in the short run than underwriting local productions to fill schedules and attract audiences. Subsequent findings by Varis (1984) provided equally interesting evidence that other countries were also major producers of programming for international distribution within regional markets; these included Mexico, which distributed throughout Latin America, and Lebanon and the United Arab Republic, who were major producers for the Middle East. Still others, like India and Brazil, had robust internal industries, which subsequently developed into vigorous export markets. Since the pioneering work by Nordenstreng and Varis, vital regional geolinguistic markets – such as Japan, which is a major supplier throughout Asia and South Asia and has a global reach that includes the West, Egypt, which supplies to the Arab world, India to the Indian populations in Africa and Asia, and Hong Kong and Taiwan to the Chinese-speaking population – have developed based on common cultural, linguistic, historical, and geographic similarities (Sinclair et al., 1996).

Statistics like those from UNESCO about television markets abroad were the basis for early and compelling assertions of US cultural imperialism by communication scholars (Schiller, 1976). A more recent (1990s) version of these concerns is the work by media scholars who study the internationalization of media conglomerates as purveyors of US cultural hegemony, global cultural homogenization, and cultural synchronization (Herman and McChesney, 1997; McChesney, 2004; Miller et al., 2001). Even more recently, there is renewed interest in programming content, which, it is argued, foregrounds neoliberal values such as consumption (Couldry, 2010); this is yet another iteration of a macro-oriented, top-down approach.

Arguments like these are often provocative and compelling, and they can be a helpful starting point for trying to understand key questions about the power of national media culture around the world and the landscape of diverse media markets. However, too often discussion of global media ends rather than starts at questions of imperialism (Tunstall, 1994). Their generally macrooriented, top-down analyses note the increasing power and scope of a small number of media corporations around the world; however, this is a problem because broad statistics about the distribution of shows or the ownership of conglomerates, although interesting and obvious, also locks us into assumptions and narrows our explanations and understanding of the global market. Important questions are missed when one focuses only on the broad picture of television trade flows or industry consolidation, especially in such an unpredictable market (Cantor and Cantor, 1986). For instance, although national industries have developed many business strategies that include coproductions and the selling of formats (TV show concepts that are repackaged to suit particular (national) markets and tastes (Freedman, 2003)) in an attempt to systematize revenue from abroad, even these arrangements are subject to the vagaries of potential buyers who must be responsive to cultural proscriptions and policies, as well as to audience preferences (Esser, 2010). Also left undetermined is why specific programs are marketed, adopted, or rejected by distributors. Even larger questions loom about how television programs are transformed at the local level in diverse international contexts of reception and interpretation.

This theoretical gap directs us to so-called middle-range approaches that bridge micro- and macroconcerns and target mesolevel conceptualization, evidence, and analysis (Sinclair et al., 1996). Mesolevel analysis attends to the concrete operational and cultural logics of global television markets: the features and operations of the marketplace rather than the market per se; the cyclicality of the forms and practices of the business of the industry rather than a presumed teleological development; industry participants who are located at all levels of organizational settings rather than just industry leaders or other highly visible decision makers; and the possibility that television series are malleable cultural products rather than immutable texts with inherent meanings (Bielby and Moloney, 2008). In short, it is necessary to study not only the production of television/video cultures, but also their distribution, and the contexts and mechanisms of their distribution, at many concrete levels (Bielby and Harrington, 2008). In sum, if a small number of huge media corporations now dominate the majority of media industry markets, this is a useful starting point for investigation of global television ownership and control and its consequences. But research must move beyond this important starting point. A useful research focus would be seeking understanding of the institutional logics of the organizations that make up the global marketplace for television and its video cultures, and targeting its mechanisms for managing market uncertainty in its business transactions, and, how local cultures affect these arrangements/solutions. This conceptual vantage point invites attention to organizations, participants, market features, discourses, locations, and properties of the cultural products produced (which pose a challenging management issue because they are so culturally/symbolically laden and their success or failure is so difficult to predict). More importantly, it would call for concerted attention to the locally specific ways in which such mechanisms are culturally understood, practiced, and engaged, (see Chung and Hamilton, 2001; Wherry, 2012). Finally, it would pay close attention to the consistency of findings that indicate reception by audiences is a crucial middle-range factor in this market (Gray, 2007; Kraidy, 2009; McMillin and Fisherkeller, 2009; Sanson, 2011).

Conclusion

The research reviewed here provides several challenges for future sociological research on television's video cultures. The theoretical gap noted by Grindstaff and Turow (2006) that consists of the distance between the now dominant approaches to the study of television – the political economy perspective and the cultural perspective – calls for concerted attention by scholars of culture industries. Such efforts call for a bolder approach to reading across disciplinary boundaries and attending to scholarly developments in cognate fields, while at the same time not losing sight of what is inherently sociological in that quest. For those still interested in macrolevel debates, a useful starting point might be the nuanced, encyclopedic synthesis and review of the vast body of evidence that is used to invoke notions of cultural imperialism and cultural globalization (Hesmondhalgh, 2007; Mirrlees, 2013). For those interested in the fertile opportunities for expanding conceptualization of the middle range of television's video cultures related to globalization and cultural production, there is useful work by cultural geographers who study regional/urban agglomerations of cultural production and distribution (see Scott, 2005, for example). There is also useful work by media studies scholars who examine how the institutional logics of politics and markets of other countries thwart television distribution (Curtin, 2005). For those interested in closing the theoretical gap in other ways lies the opportunity to explore the vastly overlooked topic of the properties of television as a cultural form (Bielby and Harrington, 2004; Mittell, 2004), the embeddedness of its form in everyday life (Lembo, 2000), and its critical appraisal and analysis (Bielby et al., 2005). Together, these topics made up an important part of early scholarship on television (see Boddy, 1990), which has, regrettably, been all but abandoned and yet remains pivotal to understanding television's ubiquity, popularity, societal penetration, and global presence. In conclusion, regardless of how or where one enters the gap, what is essential is building out from more established lines of thought and traditions and finding new challenges and opportunities for empirically grounded insights.

Vienna Circle: Logical Empiricism

Friedrich Stadler, Institute Vienna Circle (Institut Wiener Kreis), University of Vienna, Wien (Vienna), Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Vienna Circle of Logical Empiricism or Logical Positivism, sometimes better known as 'Schlick-Circle,' is described as a philosophical movement between the two World Wars in Vienna with its main proponents and its theoretical program based on the manifesto of 1929 covering 'scientific philosophy' and 'scientific conception of the world.' On the one side, the international networking and acknowledgment is characterized, and at the same time the marginalization in Austria and Central Europe caused by the rise of Fascism and National Socialism, on the other, which resulted in the forced migration and placement in the Anglo-Saxon world. As one typical member of this movement Otto Neurath is characterized, who was also dealing with sociology, the social sciences including picture language, although the Vienna Circle is mainly known by its focus on logic, mathematics, and the natural sciences.

The Vienna Circle

The Vienna Circle (as the so-called Schlick Circle) consisted of a group of about 36 thinkers coming from the natural and social sciences, logic, and mathematics, which met regularly in Vienna between the two World Wars to discuss philosophy and its relation to the sciences. The work of this group constitutes one of the most important and most influential philosophical contributions of the twentieth century, in particular in the development of analytic philosophy and history and philosophy of science (Stadler, 2001, 2003a; Richardson and Uebel, 2007).

Prior to World War I, the predecessor of the later Vienna Circle (the 'First Vienna Circle') had begun to take shape both as an organization and as a philosophy (Uebel, 2000). Within a discussion circle (inter alia, with Frank, Hahn, and Neurath) at a coffeehouse, traditional 'academic philosophy' grew more scientific. This so-called 'First Vienna Circle' met regularly as of 1907 to discuss the synthesis of empiricism and symbolic logic as modeled after Mach, Boltzmann, and the French conventionalists (Pierre Duhem and Henri Poincaré). This was also seen as an indirect answer to Lenin's polemical remarks against Mach in his book, *Materialism and Empirio-Criticism* (1909), which remained very influential in Eastern Europe up to the Velvet Revolution of 1989–90.

This early phase in the development of logical empiricism can also be interpreted as an anti-Cartesian turn in epistemology and philosophy of science, which undermined both the synthetic a priori and the secure foundations of knowledge. In the middle of the permanent crisis of philosophy between reform and revolution in society and science, the further development of this 'scientific philosophy' had, in any case, been initiated.

The Vienna Circle was first publicly announced in 1929 with the publication of what came to be called its manifesto, *Wissenschaftliche Weltauffassung. Der Wiener Kreis* (*The Scientific Conception of the World: The Vienna Circle*), edited by the Verein Ernst Mach (Ernst Mach Society) and authored by Rudolf Carnap, Hans Hahn, and Otto Neurath (Carnap et al., 1929). This group was essentially a modernist movement, at the center of which was the so-called 'Schlick Circle,' a discussion group organized in 1924 by Moritz Schlick. Rudolf Carnap, Herbert Feigl, Philipp Frank, Kurt Gödel, Hans Hahn, Otto Neurath, Felix Kaufmann, Viktor Kraft, Karl Menger, Friedrich Waismann, and Edgar Zilsel belonged to its inner circle. Their meetings were also attended by Olga Taussky-Todd, Olga Hahn-Neurath, Rose Rand, Gustav Bergmann, and Richard von Mises, and on several occasions by visitors such as Hans Reichenbach, Alfred J. Ayer, Ernest Nagel, Willard Van Orman Quine, and Alfred Tarski. Members of the periphery, most of them as participants and occasional guests, were Egon Brunswik, Karl Bühler, Josef Frank, Else Frenkel-Brunswik, Heinrich Gomperz, Carl Gustav Hempel, Eino Kaila, Hans Kelsen, Charles Morris, Arne Naess, Karl Popper, W.V.O. Quine, Frank P. Ramsey, Kurt Reidemeister, and the alleged 'genius,' Ludwig Wittgenstein, who was not attending the Schlick Circle but only regularly with Schlick and Waismann and had a special influence on some members of the group. In addition, the mathematician Karl Menger organized in the years 1926–36 an international 'Mathematical Colloquium,' which was attended by Kurt Gödel, John von Neumann, and Alfred Tarski among many others (Menger, 1994).

This international and interdisciplinary discussion circle was pluralistic and committed to the ideals of the Enlightenment. It was unified by the aim of making philosophy scientific with the help of modern logic on the basis of experimental and everyday experience. The general aims of the movement were expressed in its publications such as the two book series, *Schriften zur Wissenschaftlichen Weltauffassung* (*Publications on the Scientific Conception of the World*) 1929–37 with 11 volumes, *Einheitswissenschaft* (*Unified Science*) 1933–38 with seven volumes, the journal *Erkenntnis* 1930–40 (the 1939 volume was called *Journal for Unified Science*), and the *International Encyclopedia of Unified Science* 1938–70 (Neurath et al., 1971).

Given this story of scholarly success, the fate of the Vienna Circle was tragic. The Verein Ernst Mach was suspended in 1934 by Austro-Fascism for political reasons; Schlick was murdered in 1936 by a fanatic student, and around this time, many members of the Circle were forced to leave Austria for racial and political reasons. Thus, soon after Schlick's death, the Circle disintegrated. As a result of the emigration of so many of its members and adherents, however, the Circle's ideas became more and more widely known, especially in

Northern Europe, Britain, and North America, where they contributed hugely to the emergence of modern philosophy of science (Timms and Hughes, 2003; Hardcastle and Richardson, 2003; Manninen and Stadler, 2010). In Germany and Austria, however, the break that was caused by the forced emigration of the Vienna Circle's members was felt in the philosophical and mathematical scene for a long time (Heidelberger and Stadler, 2003; Stadler, 2010a,b).

The name 'Vienna Circle' was suggested by Neurath and was supposed to have a pleasant connotation similar to the 'Vienna Woods' or the 'Viennese Waltz.' At the same time the term was to indicate the origin of this philosophical movement and its collective orientation (Frank, 1949). In the programmatic essay of 1929 the position of the antimetaphysical 'radical' left wing around Carnap, Neurath, Hahn, Frank, and others, was especially prominent. This group supported the idea of a physicalist unity of science, most commonly referred to as 'logical empiricism' as found later in the program of the *International Encyclopedia of Unified Science* (Neurath, 1945/1946). By contrast, the more moderate wing of the Vienna Circle around Schlick, Waismann, Feigl, and others, emphasized their adherence to a dualism of science and philosophy with different names like 'consistent empiricism' (Schlick, 1950) or 'logical positivism' (Kraft, 1950).

The widely used term 'logical positivism' actually originated in Blumberg and Feigl's (1931) article with that title which was published in the *Journal of Philosophy*. Here both authors gave a concise description of the new anti-Kantian synthesis of logical and empirical factors proclaiming the impossibility of synthetic a priori truths. They went on to describe the philosophical transformation from the old to the new positivism with the adoption of symbolic logic, epistemology, and research into the foundations of science. Finally, they explained, following Wittgenstein, "the purpose of philosophy as the clarification of the meaning of propositions and the elimination of … meaningless pseudo-propositions" (Blumberg and Feigl, 1931: 269).

Proponents of 'scientific philosophy' thought of philosophy not as an autonomous discipline existing prior to science but as a critical discipline dependent upon the results of the natural and social sciences, logic, and mathematics. Turning around Kant's dictum, they claimed that philosophy without science is empty, and science without philosophy is blind. Adoption of this scientific conception of philosophy does not, however, determine what epistemology, methodology, and ontology one is committed to. Nonetheless, all adherents of scientific philosophy demanded exact methods, a critical attitude, and a more or less empirical orientation. They opposed irrational and theological systems of philosophy (*Systemphilosophie*) and viewed science in general in a positive way.

Historically, Mach's philosophy provided the foundation for the development of the positions adopted within the Vienna Circle. The term 'logic of science' (Carnap's 'Wissenschaftslogik'; Carnap, 1934), known since the mid-1930s as 'philosophy of science,' was later used to describe these positions. This implied a general scientific conception of philosophy as well as an attempt to provide a philosophy for all sciences (including the humanities). In addition, within the Vienna Circle, philosophy was regarded both as a form of linguistic analysis and as a discipline drawing on the foundations of the natural and social sciences.

At the same time there were divergences of philosophical approaches within the Vienna Circle. Those such as Schlick defended a methodological dualism of philosophy and science and those such as Carnap and Neurath sought to integrate philosophy altogether within a scientific conception of the world or encyclopedic unity of the sciences. In Schlick's view, the classical philosophical positions of empiricism and rationalism were integrated with the help of modern logic and mathematics, but a distinction between philosophy and science still remained. Neurath's more radical physicalism or 'encyclopedism' of logical empiricism aimed at overcoming philosophy itself within his collective project of an *International Encyclopedia of the Unity of Science* (Neurath, 1945/1946). This divergence in philosophical approaches left room for debates within the Circle on such topics as the merits of phenomenalist and physicalist languages, coherence and correspondence theories of truth, logical syntax and semantics, verification and confirmation, and ideal and natural languages. At the same time there was a certain consensus on the merits of logical analysis of language, a fallibilist epistemology, a scientific attitude to the world, and the unity of scientific explanation and knowledge in general.

The rivalry between Schlick's 'consistent empiricism' and Neurath's physicalist (later empiricist) unified science is a complex matter. Certain views were shared by both, such as the view of philosophy as a critique of language in accordance with Wittgenstein's philosophy of the *Tractatus* of 1922. However, while the principle of verification, logical atomism, and the picture theory of language, are constitutive features of the entire movement, by themselves they do not characterize the Vienna Circle. Theoretical elements like logicism, verifiability, methodological phenomenalism and physicalism, a fallibilist theory of knowledge, conventionalism, and realism, together with an empiricist encyclopedism were cornerstones of the internal pluralistic development of logical empiricism from the 1930s onwards. This development also reflected the influence of Neurath's historico-pragmatic point of view within the Circle. In particular, the objection toward any dualism of 'language' and 'world' (as '*Wirklichkeitsphilosophie*') with the attendant denial of any absolute 'foundation of knowledge' (Schlick, 1934) is representative of this nonreductive naturalism and methodological holism in the spirit of Pierre Duhem's and Henri Poincaré's philosophy of science. This form of relativism and naturalism already anticipated the historical turn after World War II in the philosophy of science (with Kuhn, 1962) and which contributed to overcoming the linguistic turn and the so-called 'received view' of philosophy of science.

Nevertheless, the rejection of synthetic a priori judgments remained an important element of the Vienna Circle. According to Russell and Whitehead in the *Principia Mathematica*, symbolic logic and mathematics were regarded as purely analytic and a priori (independent of any experience). Analytic truths of these kinds were contrasted with contingent statements of the natural sciences and ordinary everyday experience, as synthetic *a posteriori* judgments. But there was no further class of synthetic a priori judgments: instead there was thought to be an important class of 'meaningless' sentences, without any cognitive content. The elements of this class were seen as 'metaphysical' in the sense that they are not part of knowledge at all

even though they may express some realm of common sense experience (as a moderate summary see von Mises, 1951/1990).

This position of the classical Vienna Circle is most prominently represented by Carnap's *Elimination of Metaphysics through Logical Analysis of Language* (1931), which developed a program for a unified rational reconstruction of science. But the question as to whether an empirical basis could serve as the foundation for all knowledge received strongly divergent answers from coherence theorists about truth influenced by Neurath and correspondence theorists influenced by Schlick (Hempel, 1993). Also, the apparently strict distinction between analytic and synthetic sentences was questioned (Menger, 1979: 1–60). The ideal of one language of science, logic, and mathematics was radically weakened within the Vienna Circle itself with Menger's and Carnap's principle of tolerance long before Quine (1953) put forward his critique of the *Two Dogmas of Empiricism*. Thus, contrary to popular belief, a heterogeneous pluralism of views was in fact characteristic of the Vienna Circle: for example, regarding ethics (Schlick, Menger, Kraft), the alternatives of realism *versus* positivism (Schlick, Carnap, Feigl, Kraft, Kaufmann), verificationism *versus* falsificationism (both positions criticized by Neurath, especially against Popper's *Logic of Scientific Discovery*), and last, but not least, in matters of ideological and political preference, for example, conservative liberalism versus leftist socialism. In the later period of the Vienna Circle the contested verification principle was gradually abandoned and replaced by some form of a probabilistic confirmation methodology based on the principle of 'connectibility' (von Mises, 1951).

The unity of science movement with its six 'International Congresses for the Unity of Science' (1935–41) and the ambitious publication project 'International Encyclopedia of Unified Science' (1938–70) had a broader cultural meaning and goal, most notably the attempt to improve the human condition and to promote social reform and the intellectual struggle against irrationalism and totalitarian *Weltanschauungen*. It was a manifestation of a late Enlightenment conception of science with a socially inspired antimetaphysics. Between the two World Wars metaphysics was seen as a correlative feature of German idealism as well as of (Austro-) fascist 'universalism' as represented by the economist Othmar Spann.

The practical impulse behind this therapeutic destruction of metaphysical systems, then, was the desire for a scientific attitude based on human experience, directed against the *Zeitgeist* of totalitarism and cultural pessimism (as criticized already by Neurath in 1921a and 1931). Therefore, traditional philosophy, first of all, had to be reduced to a critical analysis of language, because most proponents of logical empiricism thought that an exact and sober usage of the scientific language is a precondition for all problem-oriented philosophizing – and moreover a sort of moral obligation.

Social criticism and collective work in philosophy of science formed a programmatic unity striving for a sweeping improvement of the human condition. Whereas in the natural sciences considerable progress had already been made, the situation in the social and cultural sciences was not so transparent, and influenced by the ongoing *Methodenstreit* since the turn of the century (Kaufmann, 1936). Although some members of the Vienna Circle like Kaufmann, Neurath, and Zilsel contributed essentially to this neglected field, their publications have been largely ignored in the historiography on the Circle for a long time. In this respect it is worth mentioning that, after the disintegration of the Vienna Circle, its former members still occasionally made reference to the 'scientific conception of the world' when speaking about general ideological questions. For example, Carnap spoke about 'scientific humanism' as a view shared by the majority of the logical empiricists (Carnap, 1963: 81ff.).

After the dissolution of the Vienna Circle, the forced migration of most of its members and the dispersion of the logical empiricist movement from its centers in Central Europe, the twin aims of a transformation of philosophy and the establishment of philosophy of science could only be envisaged once the ties to their previous cultural context and audience had been severed. But even in these difficult times the proponents of the exiled Vienna Circle organized six well-attended prestigious international conferences, the 'International Congresses for the Unity of Science': Paris (1935 and 1937), Copenhagen (1936), Cambridge, UK (1938), Cambridge, Massachusetts (1939), and Chicago (1941). One can thus say that the demise of the Vienna Circle in the German-speaking world was accompanied by the transformation of Viennese '*Wissenschaftslogik*' into philosophy of science in the Anglo-Saxon scientific community converging with North American currents like (neo)pragmatism.

Looking at the current historiography on the Vienna Circle, one can quickly recognize the difficulty of providing a representative description of the Circle and of logical empiricism in its entirety. Even the autobiographical accounts of Vienna Circle members since the classical period of the Schlick Circle show a remarkable variance – depending on focus and underlying motivations.

What these texts have in common is the refutation of metaphysics as well as of philosophy as a discipline in its own right. As an alternative, one finds a tendency toward a (physicalist) unified science that later culminated in an empiricist encyclopedia project and that includes the principle of tolerance as applied to logic and scientific languages. Already here, the contours of epistemological options emerge. If one also takes into account that the manifesto represents only one variant of the Vienna Circle at the end of the 1920s, then it becomes amply clear that there existed only a limited consensus.

In addition, it is obvious that neither the autobiographical accounts of contemporaries nor the historical accounts originating shortly after 1945 were able to provide an adequate picture of the Vienna Circle. Moreover, there exists only a partial, albeit broad, overlap of the concept of Vienna Circle with that of logical empiricism in general when one takes into account the related movements of the Berlin Circle around Hans Reichenbach or the Warsaw Group around Alfred Tarski (Danneberg et al., 1994).

Despite this pluralism is it still possible to find a sort of basic agreement here – one that unites the members of the Vienna Circle – both the central figures and those on the periphery? First of all, it is a way of philosophizing based on linguistic analysis and a great amount of problem-oriented, open-ended discussion. This was experienced personally by Arne Naess, who focused several times on the Vienna Circle's 'thought style' which, in (not only) his opinion, leads to an

inherent "pluralism of tenable worldviews" (Naess, 2003). Secondly, the use of an unambiguous language, together with exact methods, is certainly a main legacy of the Circle and those associated with it. It is only when this exact formal approach is adopted that the content and positions can be constructively criticized and refuted – a characteristic which most current modern and postmodern philosophies lack.

The explicit and hidden history of the Vienna Circle from '*Wissenschaftslogik*' to recent philosophies of science documents the wide range, pluralism, and diversity of the its heritage and message. Be it called 'scientific philosophy' (as initiated by Schlick), 'scientific humanism' (according to Carnap), or a modern encyclopedism as a 'republic of scholars' (following Neurath), it is a guide to an intellectual journey, which continues through the present day and probably on into the future.

Otto Neurath – Encyclopedia and Utopia

The Vienna Circle is mainly known by its focus on logic, mathematics, and the natural sciences, though its effects on the social sciences are noteworthy. To illustrate the effects of the Vienna Circle on the social sciences, included here is a short biography of Otto Neurath and the impact of the Vienna Circle, through him, on Sociology.

Born 10 December 1882, in Vienna to the social reformer and political economist Wilhelm Neurath, Otto Neurath attended school in Vienna and later in Berlin (at the recommendation of Ferdinand Tönnies), where he studied mathematics, political economy, and history. In 1906, he completed his military service and from 1907 to 1914 he taught political economy at the Neue Wiener Handelsakademie (New Vienna Trade School). In 1907, Neurath married the social scientist and feminist Anna Schapire (1877–1911), who died from complications related to the birth of their son Paul. In 1912, he married the blind mathematician Olga Hahn and they jointly published mathematical articles before World War I. This period also encompassed the early philosophical and scientific activities in the 'First Vienna Circle' together with Hans Hahn and Philipp Frank, with whom he maintained private and scholarly contacts until the interwar years. Prior to 1914 he also published sociological studies, inter alia, on the so-called 'theory of war economy' and on the economical situation in the Balkans, to which he took a number of study trips with the support of a grant awarded by the Carnegie Foundation for International Peace.

Following the outbreak of World War I, Neurath served on the east front and in Vienna. He was appointed director of the German war economy museum in Leipzig and at same time he worked in the war economy section of the war ministry in Vienna. In this period Neurath developed his theory and practice of graphic representation of socioeconomic relations and his natural science models. He also completed his Habilitation and became private lecturer in political economy at the University of Heidelberg with Max Weber in 1917 – a position which, due to his war service and later his involvement in the Munich 'Räterepublik,' he was never to actively exercise.

In the revolutionary phase of the postwar period Neurath became head of the Central Planning Office in Bavaria, where as 'social engineer' he had futilely tried to carry out his vision of full socialization on the basis of an economy in kind in 1919. After the movement was suppressed, Neurath was sentenced to one and a half years imprisonment for 'aiding and abetting high treason.' After 6 weeks of detention – during which he wrote his *Anti-Spengler* book – he was able to travel to Austria on Otto Bauer's intervention, but he was no longer permitted to enter Germany (until 1926) and thus also lost his lectureship in Heidelberg.

After his return to Vienna, Neurath devoted his efforts to social economy and the settlement movement in Viennese communal politics. In 1920, he became secretary general of the organization for settlement and allotment movement. In 1923, he founded the Museum for Settlement and City Planning and, from this he developed the Social and Economic Museum in Vienna (1924–34). Here he, together with an interdisciplinary team, developed his 'Viennese method of pictorial statistics' as a highly effective tool for adult education. In addition to experts from various fields, he also collaborated with artists and constructivist graphic designers (most notably Gerd Anrtz). As an architect he was able to secure his old friend Josef Frank, and as collaborator Marie Reidermeister, the sister of the mathematician Kurt Rademeister. During the same period, he had contacts with the Bauhaus in Dessau. Still in Vienna, Neurath attempted, in view of the emerging fascism, to promote the internationalization of pictorial statistics by founding branches and institutions abroad. After he emigrated in the wake of the events of the Austrian civil war of 12 February 1934, the 'Foundation for Visual Education' in The Hague was to become the platform for the further activities of the encyclopedia movement and pictorial pedagogics. There, under the most difficult conditions, he continued his work on the project known as International System of Typographic Picture Education (Isotype). His wife Olga Hahn died in 1937 in Holland from complications after a kidney operation.

At the beginning of the 1920s, still during his Vienna years, Neurath resumed his philosophical work from before World War I and was actively involved in the Vienna Circle and further circles in Neurath's private apartment and at the Social and Economic Museum. Important highlights of these activities were his initiation of and collaboration on the manifesto *Wissenschaftliche Weltauffassung: Der Wiener Kreis* (Scientific World View: The Vienna Circle) in 1929, which he wrote with Hans Hahn and Rudolf Carnap, and the founding and organization of the Ernst Mach Society/Verein Ernst Mach (1928–34), the organ for the popularization of the Vienna Circle in connection with the Vienna school reform and adult education movement. Neurath was also active as a teacher at Vienna's Workers' University, in the labor union movement, and at diverse adult education institutes, in particular at the Ottakring 'Volksheim.' Finally, as the main representative of the so-called 'left wing' of the Vienna Circle, Neurath was the leading figure for public relations and – increasingly after 1934 – for the internationalization of logical empiricism (1935–41: with six International Congresses for the Unity of Science in Paris, Copenhagen, Cambridge, Harvard, Chicago). In this context, he founded the Institute for the Unity of Science in The Hague.

In 1940, after German troops invaded the country, Neurath undertook a second adventurous flight to England, where he was interned on the Isle of Man. He subsequently established

another Isotype Institute together with Marie Reidemeister, whom he married in 1941. From 1941 to 1945 he worked as a lecturer at the University of Oxford. He served as a consultant of the city of Bilston in a city renewal project and edited the book series *Unity of Science* and *Encyclopedia of Unified Science* from 1938 on.

Otto Neurath died of heart failure on 22 December 1945, in Oxford.

Otto Neurath was one of the last polymaths of the now lost old Austrian scientific culture, is slowly but continuously being rediscovered (Sandner, 2014). This process of rediscovery is taking place on an international and interdisciplinary level although it is still a selective process and happens at varied pace intervals. It seems not to be due merely to chance that this exercise in intellectual archaeology takes place in our era between Modernism and Postmodernism.

Neurath would, on principle, have rejected the title 'Universal Genius' which William Johnston awarded him (with the best of intentions) in his book *The Austrian Mind* (Johnston, 1972).

For Neurath knowledge was always a collective enterprise embedded in an all-encompassing social context. Throughout his life he never jettisoned his enlightened view of a social and cognitive totality. For him the discovery and explication of seemingly disparate connections between phenomena, both in terms of text and image, and the development of lines of argument based thereon was an essential precondition for all intellectual work. To view science as an end in itself was totally alien to him. He believed that knowledge – even as part of a hardly predictable historic process – should serve life in all the areas between the poles of everyday life and specialist research activity. This concept of reflective science will be surprising only to those who have been taken in by the clichéd images of the so-called *positivism debate* or that about the *one-dimensional society* (Marcuse, 1964; Dahms, 1994). Both these distortions absolutized individual elements of Logical Empiricism and used them to form a hostile portrait by dialectic magic. On the other hand, traditional academic metaphysics, obsessed with the subtleties of meaning and oblivious to the consequences of material being feels equally challenged by the radical and down-to-earth 'scientific world conception' clothed in the garb of the neo-Enlightenment, which Neurath promoted.

It is not easy to approach the complex and highly diverse life-work of Otto Neurath without getting lost in details, on the one hand, or without, on the other, resorting to inadequate generalizing descriptions such as 'positivist,' 'physicalist,' 'Austro-Marxist,' etc. How can one obtain an overview of a man, both of theory and practice, who covered the entire spectrum of knowledge including architecture, economic history, mathematics and logic, philosophy, history and theory of knowledge, visual education, and museology in about 300 publications (including around 30 monographs and books), and who worked in at least four countries (Austria, Germany, The Netherlands, England) as a social scientist and teacher at commercial colleges, workers' colleges, adult education schools, and at universities, a man who pursued a demanding profession (as museum director), yet also figured centrally in the Vienna Circle?

It seems that the answer to this question lies in Neurath's principle of thinking and acting: to proceed from incomplete and unstable elements temporarily united in theory and its related practice, and to employ, under the constraints of uncertainty and mere probability, the criteria of empiricism without ever losing sight of the fragmentary starting point or the contemplation of a historical process. This approach in itself constitutes a criticism of the idea of a fundamental and hierarchical *system* and at the same time an appeal to think in ways differing from those which prevail in society and the sciences, an appeal to risk a concrete *utopia* and to contribute to the promotion of the common good by means of cooperative *planning* for freedom and happiness. After World War I, Neurath envisaged an international 'republic of scholars,' much in the tradition of the French encyclopedists. Yet despite his optimism, he realized that the growth of Fascism and National Socialism threatened to end all these young democracies and he was not naive enough to believe that the proper proportion of rationalism and empiricism alone could reverse the 'demise of reason.' In his unpublished response to Max Horkheimer's *Der neueste Angriff auf die Metaphysik* (1937) (*The Most Recent Attack on Metaphysics*). Neurath, anticipating the main arguments against the dialectic of Enlightenment, referred to the limitations of social criticism which result from the fragility of knowledge including sociology and its history (Neurath, unpublished manuscript: 2): "What is not at all noticed at one time attracts the attention of other times and then can become the center of important considerations. […] for basically nothing is secure – everything is in flux." Moreover "we know no other authority beyond science which sits in judgement over science and studies its foundations," that is, there also is not available some form of transcendental reason. A central affinity to the standpoint of Wittgenstein's middle and late periods is unmistakable: philosophy is viewed as a language game, a game from which we cannot escape but about which we can certainly speak intelligently.

The basis for the remarkable rediscovery of Otto Neurath was laid some decades ago: in the English-speaking world the research began (motivated not least by Willard Van Orman Quine's repeated reference to the ship metaphor as an image of knowledge) with the edition of two selected volumes of Neurath's writings (1973 and 1983), whereas in the German-speaking world, besides one volume of selected works and a monograph, with the volumes of an edition of his writings; first those on philosophy and methodology (1981), then those on visual education (1991) and now those on the life and work and on economics (1996f).

In Austria an exhibition on his life and work together with a centenary symposium on Neurath (in conjunction with that on Moritz Schlick), held in 1982, augmented the new interest by the public and scholars. Topics which attracted this rediscovery ranged from his educational work to his economic theories, and his links to the architecture of the *Bauhaus* and the Viennese *Werkbundsiedlung* and to constructivist art (Haller, 1982; Stadler, 1982). A second main focus of interest moved toward the critical exploration of Neurath's theoretical potential and led to a reconstruction of the 'forgotten' Vienna Circle (Uebel, 1991, 1992, 2007). As a result of all this activities, we can now state that the depiction by others and even self-descriptions of 'logical positivism' after 1945 – especially of Neurath's role – were derived from appalling inadequacies and prejudices. For

many innovations of current history and philosophy of science were, in fact, anticipated in Neurath's oeuvre. The rediscovery of Neurath is therefore not merely a phenomenon of academic nostalgia, but itself constitutes research into the conditions and possibilities of changing a paradigm in the philosophy of science (see recently Cat, 2010).

The process of reassessment did not occur only within the narrow confines of philosophy and the theory of knowledge, but the most abstract structural context of Neurath's various subjects which, on first glance, seem all too disparate and range from the *Encyclopedia of Unified Science* to the picture language and his museology and visual education. From the start, Neurath himself had underlined the essential unity of his patterns of thought and of action. Not only are holism in philosophy of science (Duhem-Neurath-Quine principle) and naturalism extending to the "orchestration of the science by the encyclopedism of logical empiricism" (Neurath, 1945/1946) and their precise formulation pursued as systematically as his interest in visual education and the Viennese method of visual statistics and the *Isotype*. Loose but deliberate analogies can be found in Neurath's original writings, as can attempts to apply his theoretical concepts to education, social reform, and the politics of knowledge (Heinrich et al., 2011; Kraeutler, 2008; Neurath, 2013).

The following areas must be seen from this point of view: economy in kind, war economics, planning theory as well as his involvement in the Bavarian Revolution, the Viennese housing movement and town planning projects in England, not to mention his visual education projects and the founding of the 'Social and Economic Museum in Vienna' and of the 'International Foundation for Visual Education' in Holland (The Hague). Thus Neurath also emphasized several times, in a reference to Leibniz and Comenius, that the future encyclopedia did not aim merely at a standardization of the *language of science* but also at a standardization of the *visual representation* (he projected 26 volumes of text and a 10 volume 'visual thesaurus'). This combination of text with visual language had already been realized in part in his publications *Fernunterricht* (1931–33) and his successful book *Modern Man in the Making* (1939). Toward the end of his life Neurath referred to the 'mosaic of the sciences.' In the spirit of this formulation we can arrive at an understanding of his life's work by means of a kind of collage, employing the regulative idea of the unity of science and society – a term that is most appropriately used as the subtitle to the latest volume of selections from his work (P. Neurath and Nemeth, 1994). Neurath's phrase of a 'mosaic of sciences' also contains (long before C.P. Snow's well-known critique) an implied criticism of distinct (second and third) scientific cultures.

The biography of Otto Neurath is marked by the historical caesuras of 1918/19, 1934, and 1938/40, which brought major interruptions to his work. The fact that he nevertheless carried on between destruction and reconstruction under the most trying circumstances can offer encouragement and indicate that, even in a hostile environment the humanization of knowledge can make a modest contribution to the democratization of society (Nemeth and Stadler, 1996).

First, there is Neurath's vision of a joint reconstruction of the enterprise of sciences, which, poetically formulated, reappears in different variations throughout his work (Neurath, 1921b/1973: 199).

> We are like sailors who on the open sea must reconstruct their ship but are never able to start afresh from the bottom. Where a beam is taken away a new one must at once be put there, and for this the rest of the ship is used as support. In this way, by using the old beams and driftwood the ship can be shaped entirely anew, but only by gradual reconstruction.

Then there is the ethos with which Neurath pursued this reconstruction. In the middle of the revolutionary postwar phase, Neurath delivered an analysis of the *Zeitgeist* which, particularly in our present times of change, gives us reason to reflect (Neurath, 1919/1981: 137f.).

> How often has the word "utopian" been said with a tone of soft disdain or commiserating recognition! However stood on the ground of what happens to be the present and only knows it, sat in judgement over he who tried to glance behind the curtain of the stage of fate, who went to pains to prepare the game of the future. Now the curtain is being raised, clumsily the actors emerge from behind the scenes. Unknown figures meet unknown figures and unknown things. Some try to feign ease, others look at the prompt boxes and listen gratefully to the utterances coming from there. Rathenau, Atlanticus, Popper-Lynkeus and others are suddenly no longer simply 'utopians', but social engineers who were ahead of their times. From all corners we now hear catchwords and demands which we find in Fourier, Cabet, Bellamy, even in Thomas Morus or Plato. The utopia today are the only attempts at total constructions of social engineering at our disposal. Whoever does not want to meet completely unarmed the innumerable stimuli and endeavours breaking over us today, should read the utopia which until now has been dealt with only marginally by economics.

Finally, there is the consistency and continuity of his thought. In his intellectual testament, where Neurath (1946: 526f.) states

> I always promoted monism as a means of empiricist communication and I promoted pluralism as an attitude in making hypotheses. I have contended with thinkers of all kinds who tried to declare one system as marked out before others and therefore I tried to convey the insight that we need a kind of 'decision' wherever we have to make a "choice," even when we are trying a scientific theory [...]. One may evolve more than one theory of light starting from the same basis, as one may plan more than one holiday tour from the same starting point.

Note: This article is an abridged and updated version of my article on the Vienna Circle in: James Robert Brown, 2012; The general background for this entry in Stadler (2001) and in the publications of the Institute Vienna Circle: www.univie.ac.at/ivc.

Abstract

The Vietnamese revolution combined a nationalism-inspired struggle against Western powers and a collectivism-oriented socioeconomic transformation within Vietnam. It reached its peak from 1945 to 1986. This article provides a historical background on the Vietnamese revolution, the processes of revolutionary transformation in Vietnam since 1945, and the theoretical debate in Western social sciences on the Vietnamese revolution.

In one and a quarter century since the French conquest of southern Vietnam in the 1860s, Vietnam underwent a radical transformation from a Confucian monarchy to a Marxist–Leninist state. The Vietnamese revolution involved a violent clash with two major Western powers, France and the United States, as well as a fundamental transformation of the Vietnamese socioeconomic system.

Historical Background

Citing the Vietnamese monarchy's persecution of Catholics and refusal of a trade request, France launched a series of attacks on Vietnam from 1858 onward. By 1867, France had seized as a direct colony the frontier southern third of Vietnam (Cochinchina or *Nam bộ*) from the Vietnamese monarchy. By 1884, northern and central Vietnam (respectively Tonkin or *Bắc bộ*, and Annam or *Trung bộ*) had fallen under French control, although the Nguyen monarchy nominally retained its direct administration of the latter.

In the aftermath of the French conquest, the resistance to French colonialism, mainly in the name of an 'Aid-the-King' movement, was led primarily by Confucian literati. It lasted the longest in central and northern Vietnam. By the time the Union of French Indochina was established in 1897, with Laos and Cambodia as the remaining two of the five components, the armed anticolonial resistance led by Confucian literati had virtually collapsed (see Marr, 1971).

Many members of the Vietnamese elite collaborated with the French rulers, while a number of others searched for a more effective path of resistance, strongly influenced by Chinese reformist and revolutionary thoughts and inspired by the rise of Japan as an Asian power. At one end of the collaboration–resistance spectrum in the first quarter of the twentieth century was the Confucian scholar Phan Bội Châu, a native of northern Central Vietnam, who organized a movement of students to Japan and inspired isolated armed resistance against French colonialism (Marr, 1971). In the context of strong French repression, Thailand and southern China served as important bases for exiled resistance leaders (Goscha, 1999). At the other end were many collaborators, such as the northern neotraditionalist Phạm Quỳnh, as well as many southerners who were rewarded with large tracts of land sold at low prices as the cultivated acreage in Cochinchina increased five times from 1870 to 1920 thanks to water control efforts by the French. Many of these southerners acquired French citizenship, experimented with the more open politics of the direct French colony of Cochinchina, or even played a role in the southern millenarian movements of Cao Đài and Hòa Hảo (Tai, 1983, 1992), coopting many poor peasants in the sharply stratified Cochinchina society. With the last Confucian examination being held in Vietnam in 1919, a new Western-educated elite began playing a salient role in the anticolonial resistance from 1925 onward. The major uprisings took place in northern Vietnam in 1930 under the leadership of the Vietnamese Nationalist Party (VNP), and in central and northern Vietnam in 1930–31 under the Indochinese Communist Party (ICP). The ICP-led movement in 1930–31 represented the most serious challenge to French colonialism since the Aid-the-King movement of the nineteenth century, as it involved the participation of half a million Vietnamese and threatened the colonial order in 25 provinces. At the peak of this movement, the colonial administrative apparatus virtually collapsed in many villages in the provinces of Nghệ-An (birthplace of Hồ Chí Minh) and Hà Tĩnh in northern Central Vietnam. The ICP local leadership spontaneously seized village administrations, abolished taxes, reduced rents, and redistributed up to 8500 acres of communal land in these two provinces alone.

In the short run, both the VNP- and ICP-led movements in 1930–31 collapsed under strong repressive measures by the French colonial regime with its superior military forces. Many revolutionary leaders were imprisoned, while Thailand and southern China again became important bases for exiled political activists, including Hồ Chí Minh. It was not until the release of a number of political prisoners and the introduction of a more liberal political atmosphere in colonial Indochina under the Popular Front regime in France (1936–39) that revolutionary activism gained significant momentum. In the context of the Japanese military's advance into Indochina in September 1940 and the French colonial government's subsequent collaboration with Japanese military authorities, the Vietminh (an abbreviation of *Việt Nam Độc Lập Đồng Minh Hội*, or Vietnam Independence Alliance League) under Hồ Chí Minh began building a base of operation in northern mountainous areas, working with many members of ethnic minorities, against both the Japanese and the Axis-aligned French colonial administration (Marr, 1995, Chapter 3).

Wars and Vietnamese Revolutionary Momentum

The major turning point was 1945, when French colonial power was humiliated by the Japanese-supported coup of 9 March 1945, and when in the context of a power vacuum with the Japanese surrender to Allied forces in August 1945, the Communist-led Vietminh organized the seizure of power throughout the country. The last Vietnamese monarch abdicated under revolutionary pressure. Hồ Chí Minh's Declaration of Independence from France in September 1945 evoked a powerful nationalist sentiment from all social strata, and garnered widespread support for the first independent government of Vietnam (Marr, 1995, 537–9). In the Vietnamese Marxist orthodox discourse, this seizure of power has been referred to as the August Revolution (*cách mạng tháng tám*). It was a revolution only in the narrowest sense of the term: a seizure of administrative power and an official marking of the end of the monarchical era. However, even the maintenance of this administrative power in a territorially unified Vietnam came under serious challenges by France's desire to regain its influence and control of Vietnam, the complications of post-World War II international politics, and the postwar rise of U.S. power and the Cold War. France's attempt to regain control of Vietnam and its underestimation of the support for Vietnamese independence led to the Franco-Vietnamese war from 1946 to 1954. The United States' greater concern with Europe and Soviet influence after World War II, in combination with Chinese Communists taking control of mainland China in 1949, shifted U.S. policy toward a support for France and away from U.S. President Franklin Roosevelt's support for the independence of colonized peoples in Asia and Africa. The violent Franco-Vietnamese war ended in 1954, after the Vietminh defeated the French at Điện Biên Phủ in the northern highlands. Vietnam was temporarily divided into two parts at the 17th parallel, with the north under Communist control and the south under American influence.

Hồ Chí Minh's vision of a unified Vietnam was not achieved until 1975, after a long and violent war that, in the context of the Cold War, involved a massive U.S. ground involvement in South Vietnam and U.S. bombing of the north and parts of Laos and Cambodia. The Vietnamese Communist Party began lending support to the armed resistance against the U.S.-allied government in Saigon in 1959, helped to establish the National Liberation Front of South Vietnam in 1960, and increased the flow of personnel and arms from the north to the south from 1960 onward (Lượng et al., 1995, pp. 285ff.). The United States responded by increasing military advisers in South Vietnam to 15 000 by 1963, bombing North Vietnam from 1964 onward, and introducing ground combat troops to South Vietnam in 1965. At its peak, the United States had half a million combat troops in South Vietnam. In the context of the Cold War, North Vietnam in turn received significant military and economic aid from the Soviet Union, China, Eastern Europe, and Cuba. The intense warfare led to the migration of millions of peasants to urban areas in South Vietnam, seriously damaged the South Vietnamese economy, and increased the dependence of the U.S.-supported South Vietnamese government on U.S. aid.

In the United States, the draft system and the protracted warfare in Vietnam, exposed daily in the mass media, intensified the antiwar movement, especially among the young. This contributed to the U.S. policy of handing the war to South Vietnamese troops, and to the withdrawal of U.S. ground troops and the end of bombing North Vietnam by 1973 in the aftermath of the Paris Peace Agreement. South Vietnam enjoyed no peace, as the Paris Agreement was violated by both the Saigon government's troops, on the one hand, and the North Vietnamese troops and their southern allies, on the other. The U.S.-supported government in South Vietnam eventually collapsed in April 1975, under the attack of North Vietnamese troops and their southern allies.

Vietnamese Marxists' consolidation of political control (in the north by 1954 and in the entire country by 1975) strengthened the foundation for the enactment of their socioeconomic vision. In North Vietnam, the socioeconomic revolution accelerated throughout the 1950s under a Communist vision of a collectivized economy where the state played the dominant role in industrial and agricultural production, as well as in the distribution of raw materials and finished products. By 1965, the northern economy was based mostly on the state and cooperative sectors, and sustained by aid from the socialist bloc, as North Vietnam became directly involved in the war against the United States and the American-supported government in Saigon. The Communist party's economic vision was imposed on the south after 1975. The economic crisis in the late 1970s, fueled by the resistance of peasants in the southern Mekong Delta to collectivization and the disenchantment of northern cooperative farmers, led to a gradual shift toward a market economy. This process of economic reforms (*đổi mới*) started in agriculture in 1981. The economic reform was reaffirmed at the 1986 Communist Party Congress, and implemented in the rest of the economy by 1989. Cultivators in the north consequently have had long-term leases on agricultural land since 1994, and they have regained control over production and distribution processes. In the southern third of the country, land has been under *de facto* private ownership again since 1988, although the principle of collective ownership is reaffirmed in Vietnam's 1992 constitution (Article 17) and various land laws. Private industrial and commercial enterprises as well as large private plantations have been allowed to re-emerge.

Foreign direct investments since 1988 have helped to fuel generally strong economic growth, which averaged 7.3% annually in the 1990–2010 period. Vietnam has moved from being one of the poorest countries in the world in 1990 to joining the lower level of middle-income countries by 2008. Poverty has been greatly reduced. Although Vietnam is still a one-party state officially committed to socialism, socioeconomic inequality has sharply arisen.

The Vietnamese Revolution: Theoretical Debates

Many an important theoretical model on revolution has been constructed partly on the basis of scholarly knowledge of the Vietnamese revolution, a revolution that combined a nationalism-inspired struggle against Western powers with a collectivism-oriented socioeconomic transformation within Vietnam, and that reached its peak from 1945 to 1986. These models are embedded in the major traditions of contemporary Western social theory (John Stuart Mill, Karl Marx, and Emile

Durkheim). In the literature on revolution and agrarian unrest, the political scientist S. Popkin's rational choice model offers a good example of a theoretical model within the Millean tradition of inquiry (Popkin, 1979). It considers the behavior of both the peasantry and the elite as the goal-directed acts of self-interested individuals. Popkin argues that modern revolutionary movements such as the Vietminh succeed because, as political entrepreneurs, their leaders can offer peasants concrete welfare improvements and effective organization against the marauding lords and notables of the old order (cf. Race, 2010: chapters 4 and 7; see also Montesano, 2011). He emphatically rejects the view that modern agrarian movements involve defensive reactions to the violation of precapitalist normative structures by the colonial and capitalist order. In Popkin's argument, the incorporation of indigenous agriculture into the capitalistic world market, the establishment of the colonial regime, and the expansion of state power are not necessarily deleterious to peasant welfare. According to Popkin, colonialism brings vital stability and an improved communication system that keeps prices from fluctuating widely and thus keeps peasants alive in times of local famine.

Intriguing as it is, Popkin's model encounters its share of empirical anomalies in the Vietnamese case. For example, on which matrix of material costs and benefits did a large number of Vietnamese from different social strata base their decision to volunteer for the Vietminh armed forces in 1946–50? Recall that this was when Vietminh troops faced an enemy of overwhelmingly technological superiority, and it was before poor recruits could foresee any substantial socioeconomic reforms in their favor.

In contrast to the Millean tradition of inquiry, the Marxist tradition seeks to situate economic transformation and revolutionary movements within the structure of conflict-ridden class relations. Both Western and Vietnamese Marxist analysts consider Western capitalist expansion as the root of the Vietnamese revolution. In this perspective, French colonialism in Vietnam as the representation of Western capitalist interests sought the maximal return on capital at the expense of the native working classes. The sociologist Martin Murray argues that capitalist exploitative measures included the concession of indigenous land to colonial settlers for the development of major cash crops; the introduction of direct and indirect taxes, and the conversion of tax payments from kind to cash to facilitate capitalist growth; and the oppressive appropriation of labor through the corvee system, the maintenance of rural labor reserves in Tonkin and Annam, and repressive labor laws to hold down labor costs for capitalist agro-mineral ventures. Murray suggests that the impact of world capitalism was far from uniform in Vietnam. It was most striking in Cochinchina, which emerged as one of the top three rice-exporting areas in the world, where approximately two-thirds of the rural population were separated from the means of agricultural production, where land and labor became strictly commodified, and where classes became increasingly differentiated. In contrast, in the north and center (Tonkin and Annam), although the rural population was increasingly drawn into market relations, the majority still tenaciously held onto their minuscule land holdings, buffered in many communities by their small shares of communal land. In North and Central Vietnam, the proportions of inalienable communal land averaged, respectively, 21% and 25% of the cultivated acreage. Murray suggests that the persistence of communal land in North and Central Vietnam contributed to the formation of noncapitalist labor reserves for the plantations, mines, and factories within French Indochina and beyond, reserves where workers could rely on kinship and communal ties for survival in times of recession and during youth and old age. It has been suggested that the cost of capitalist production was consequently held down because capitalist firms had to pay only the cost of short-term labor reproduction (the cost to sustain workers physically during the period of employment), and not the cost of long-term labor renewal (the cost of replacing a physically debilitated workforce with a new generation of laborers and of maintaining a temporarily idle workforce during economic downturns). In the long run, Murray suggests, "These 'blockages' to the homogeneous spread and deepening of the extended reproduction of capital coincided with economic stagnation, declining productivity, and the vicious cycle of rural poverty associated with the 'underdeveloped' regions of the globe" (Murray, 1980, p. x).

In the context of the capitalist world system, Marxist analysts consider the proletariat to be either located largely in the periphery of world capitalism, or composed of 'ethnicities' originating in the periphery; the bourgeoisie is heavily concentrated in, although by no means restricted to, the Western core. Within the Marxist world system framework, class conflict takes on an international dimension, and revolution is seen as originating in the periphery, where proletarian class interests emerge most clearly.

Within the same Marxist framework, the sociologist Jeffrey Paige suggests, "The strength of colonial and imperial political controls long prevented the political expression of these conflicts, but with the decline of colonial power in the postwar era, the commercial export sectors of the underdeveloped world have become centers of revolutionary social movements" (Paige, 1975, p. 3). Assuming inherent conflicts between agricultural producers and the dominant class, Paige attempts to construct an overall model of the forms that class conflict takes (Paige, 1975, 1983). Paige deduces these actors' behavior patterns and the form of agrarian unrest from their income sources. More specifically, he proposes that, on the one hand, the economic base of the landed dominant class is narrower, more static, and less efficient than that of its commercial and industrial counterparts. The former's economic weakness gives rise to zero-sum class conflict and its tyrannical political control of the means of production (both land and labor). On the other hand, the broader, more dynamic, and more efficient capital base of the commercial or industrial upper class can expand nonproducers' resources. This factor facilitates the adoption of more compromising solutions by the dominant class. In this context, class conflict involves the economic distribution of goods and products rather than the political control of labor and land.

Adopting Marx's theoretical arguments in his analysis of the French peasantry (Marx, 1964), Paige further hypothesizes that cultivators' dependence on land as their main source of income gives rise to a conservative, competitive, and structurally dependent peasantry. In contrast, their dependence on wages would result in a more radical, solidary, and structurally interdependent cultivator class. In the Vietnamese case, Paige's

model predicts that agrarian unrest will take the form of rebellion when both cultivators and noncultivators derive their incomes from land, as is the case in North and Central Vietnam. Furthermore, in Cochinchina, "A combination of noncultivators dependent on income from land and cultivators dependent on income from wages leads to revolution" (Paige, 1975, p. 71; Paige, 1983, p. 706). The Marxist framework has its share of empirical anomalies. First of all, the active resistance to French colonialism did gain support among numerous members of the native elite whose organizational efforts provided a crucial link among the rural communities. It is reflected in the necessity of the special category 'resistance-supporting landlord' in the land reform campaign in the north after independence. The active support of these members of the indigenous elite for anticolonial movements cannot be mechanically explained in terms of the struggle by the working classes of the periphery against the capitalists of the core. It is their nationalist aspirations that propelled them toward a path of political activism (see also Emerson, 1960; Woodside, 1976, p. 303).

Vietnam's regional variations in revolutionary strength and socioeconomic conditions present the Marxist models with a second major anomaly. In colonial Vietnam, the peasantry was most heavily dispossessed of the means of production in Cochinchina (South Vietnam). However, from the mid-nineteenth century to 1975, the armed resistance to French colonialism and capitalism was generally more limited in the south than in the north and the center. With the sole exception of the 1940 armed insurrection in certain areas of Cochinchina (cf. Paige, 1975, pp. 323–4; Toàn et al. 1985, pp. 318–9), at no point did the anticolonial armed movement in the south exceed or even approach the intensity of the unrest in the center and the north. In the pre–World War II period, it was in Annam (Central Vietnam) that the 1930–31 unrest posed the greatest threat to the colonial order. During the First Indochina War (1946–54), the French encountered considerably greater resistance in Annam and Tonkin. During the period of direct and massive American intervention (1964–75), it was not in the former Cochinchina but in the southern part of Central Vietnam that the National Liberation Front developed its strongest roots (Mitchell, 1968; Paige, 1975, pp. 326–32; Luong 1992, pp. 227–8). However, it should be noted that among Vietnam specialists writing on the Vietnamese revolution, David Hunt has a different perspective on this issue, and focuses primarily on the transformation of class relations within Vietnam. He seems to agree with Paige in arguing, "[t]he Mekong Delta [in Cochinchina] was the most revolutionary section of the country…[during the 1946–54 war] Viet Minh cadres disregarded [VCP] united front guidelines and chased away rural elites. [In the 1960s] activists in the South … showed little interest in cross-class alliances and resumed their campaign to topple 'the entire socioeconomic elite which constituted the foundation of the Saigon regime.'" (Hunt, 2008: p. 7). In other words, Hunt considers Mekong Delta cultivators revolutionary because they were class conscious, were engaged in class struggle, and did not necessarily lose their solidarity after getting land and becoming middle-class peasants (Hunt, 2003: pp. 603, 615). He considers the northern part of the country less revolutionary than the Mekong Delta because many members of the village elites in the north were allowed to join the Vietnamese Communist Party (Hunt, 2003: p. 603, 615). However, without the success of the struggle (with the support of many elite members) against Western powers, it would not have been easy for the collectivist socioeconomic revolutionary vision to be implemented. It was also in the Mekong Delta that the collectivist socioeconomic vision of the Vietnamese Communist Party encountered the greatest resistance from cultivators (see also Long, 1988; Luong, 1994).

It is a historical fact that North and Central Vietnam, despite their lesser degree of class polarization, constituted the areas with both stronger resistance to Western intervention and lesser resistance to a collectivist revolutionary vision.

While influenced to varying degrees by the Marxist approach, anthropological analyses of agrarian revolutions, and of historical events in general, have paid closer attention to the dynamic interplay between capitalism and indigenous noncapitalist social formations as sociocultural systems (Wolf, 1969).

In James Scott's moral economy model, agrarian unrest is examined in terms of the reactive response of the peasantry in a precapitalist social formation to capitalism and colonialism (Scott, 1976). In the context of the world market and the colonial state, the precapitalist order's subsistence ethic, by which lords and the state are supposed to respect peasants' right to subsistence in exchange for legitimacy, is more often violated. The expansion of Western capitalism and the establishment of European colonies led to the violation of the subsistence ethic through the erosion of patron–client ties and the existing welfare mechanisms in the relation between cultivators and noncultivators. Scott considers peasant movements quintessentially defensive reactions of a moral nature: defensive reactions against the violation of the subsistence ethic and the increasingly serious threat to peasants' survival during subsistence crises. Under this threat and violation, any significant natural or human-induced disaster potentially sparks off agrarian unrest (cf. Luong, 1985). The prominent role of Third World peasants in twentieth-century political movements, Scott argues, involves this dynamic interplay between a precapitalist sociocultural order, on the one hand, and colonialism and capitalism, on the other. Unrest is thus defined, within the Durkheimian tradition of social thought, in terms of a breakdown of the normative framework during a period of transition.

On the basis of his study of the Vietnamese revolution in a Mekong Delta province, David Elliott suggests that the dynamics of this revolution in the Mekong Delta in its earlier period were underlain by a moral economy framework, despite the fact that "the collective sense of moral community… [was] less powerful [in the Mekong Delta] than in other areas of Vietnam" (Elliott, 2003, p. 15). Over time, "the vast social dislocation of the war which atomized the rural communities [in the Mekong Delta] also strengthened the 'rational peasant' individualism of many people struggling to survive in an environment in which familiar community social mechanisms had broken down. ….[I]ndividualism cut into the base of voluntary support for the revolution, in part because the revolution had little to offer a 'rational peasant' by 1971" (Elliott, 2003, 1235; cf. Hunt, 2003, pp. 611ff.)

In the context of the strong socialist revolutionary potential in North and Central Vietnam, Luong hypothesizes

that the precapitalist tradition of the north and the center provided stronger ideological and organizational resources for active resistance to French colonialism in particular, and to capitalist imperialism in general. Despite considerable internal tension, this tradition nurtures values conducive to the growth of nationalism, to collectivism in a relatively mild form, and to a hierarchical organizational framework (Luong, 2010).

On one level, the indigenous precapitalist framework was characterized by both class cleavages, and a male-oriented and kinship-centered hierarchy. Luong suggests that the hierarchical structure of the local tradition, maintained partly through the socialization process, accounts for numerous features in Vietnamese anticolonialism and the Vietnamese revolution: the male-centered elitism in the VNP recruitment and organizational methods, the Vietminh's reliance on male members of the intelligentsia for local leadership in the early period of anti-French resistance, and the male dominance in both the domestic and public arenas in postcolonial Marxist Vietnam.

On another level, the growth of nationalism and a collectivistic vision of political economy are facilitated by important communal institutions and corresponding conceptual categories in the local traditions of the north and the center. Northern and central villages maintained sharp boundaries through villagers' participation in the collective worship of tutelary deities, an extraordinary degree of village endogamy, the institution of communal land, and a nucleated settlement pattern. In contrast, group boundaries were considerably less rigid in southern Vietnamese communities, where settlements were nonnucleated and where there existed significant geographical mobility due to the frontier environment. Luong suggests that through a sharp distinction between insiders and outsiders in the native conceptualization of kinship, communality, ethnicity, and nationality, the northern and central tradition intensified the negative reaction of many Vietnamese to any foreign intrusion on the indigenous landscape and to French domination in the colonial racial diarchy. Luong also suggests that in northern and central Vietnam, the relatively strong institution of communal land in particular, and the subsistence ethic of the precolonial period in general, nurtured a collectivist vision of political economy even among many VNP members in the 1920s, well before their exposure to Marxism. The existence of communal land and the subsistence ethic also facilitated the process of land collectivization in northern and central villages, in comparison to its very slow progress in the south from 1975 to 1985. Finally, within the corporate rural community, the extensive kinship and communal ties facilitated the mobilization of resources by local revolutionary leaders, especially the generally well-regarded members of the native intelligentsia. Luong suggests that the indigenous noncapitalist tradition thus cannot be ignored in any analysis of the Vietnamese encounter with French colonialism in particular and the capitalist world system in general (see Marr, 1971; Woodside, 1976).

Abstract

Summarized is research, primarily from the United States, arguing that violent content in mass media has small but significant impact on real-world violence. Three forms of effects, learning of aggressive attitudes and behaviors, desensitization, and cultivation of fear, are discussed, as are three theoretical models – Bandura's social learning theory, Berkowitz's priming effects theory, and Heusmann's social developmental model – for such effects. Contextual factors in effects, and the special nature of child audiences are discussed. Recent research on television content is presented, and public policy alternatives are suggested.

Public and academic concern about media's contribution to real -world violence are about as old as the mass media and the social sciences themselves (Wartella and Reeves, 1985). Despite frequent framing of the matter as 'controversial,' extensive research – an estimated 3000 (Donnerstein et al., 1994) to 3500 (Wartella et al., 1998) studies in the United States alone – have examined the impact of media violence, and a number of recent major reviews (Huston et al., 1992; Murray, 1994; see also Potter, 1999; Paik and Comstock, 1994; Comstock and Paik, 1991) have concluded that media violence plays a measurable role in real-world violence. A variety of US agencies, including the Centers for Disease Control of the US Public Health Service (1991), and medical and public interest organizations, including the American Medical Association, the American Academy of Pediatrics, and the National Conference of Parent-Teacher Associations, have identified media violence as a public health problem. The review below focuses most heavily on US research and US media, most notably American television, primarily because a large majority of the published social science research on media and violence is US research on American audiovisual media. Potter (1999, pp. 44–45), for example, reports 42 published content analyses of US television since 1954, and just 19 from the rest of the world. Moreover, American media are among the world's most violent – and most exported – and real-world violence is a recurring public policy issue. Further, much of this literature concerns impacts of media violence on children and adolescents, for the interrelated reasons that young audiences are considered the most impressionable and most vulnerable. Adults are generally viewed to be more resistant to the deleterious influences of violence, and, as some would argue (cf. Huesmann, 1997), violent behaviors in adulthood may be traced to media use during childhood.

Theories of Effect

Three models have been proposed to describe the process by which such learning and imitation of media violence occurs: social learning theory, priming effects theory, and a social developmental model of learning (Wartella et al., 1998).

First proposed by Albert Bandura in the 1960s, social learning theory is the best known theoretical account of violence effects. Bandura asserts that through observing television models, viewers come to learn behaviors which are appropriate, that is, which behaviors will be rewarded and which punished. In this way, viewers seek to attain rewards and therefore imitate these media models. When both children and adults are shown an aggressive model who is either rewarded or punished for their aggressive behavior, models who are positively reinforced influence imitation among the viewers. Even research in the field has demonstrated that aggression is learned at a young age and becomes more impervious to change as the child grows older. In a longitudinal study to examine the long-term effects of television violence on aggression and criminal behavior, Huesmann et al. (1984) studied a group of youth across 22 years, at ages 8, 18, and 30. For boys (and to a lesser, though still significant extent for girls), early television violence viewing correlated with self-reported aggression at age 30 and added significantly to the prediction of serious criminal arrests accumulated by age 30. These researchers find a longitudinal relationship between habitual childhood exposure to television violence and adult crime and suggest that approximately 10% of the variability in later criminal behavior can be attributed to television violence.

Priming effects theory serves to augment the more traditional social learning theory account of television violence effects. In the work of Leonard Berkowitz and his colleagues, this theoretical account asserts that many media effects are immediate, transitory, and short-term (Berkowitz, 1984). Berkowitz suggests that when people watch television violence, it activates or 'primes' other semantically related thoughts which may influence how the person responds to the violence on television. Viewers who identify with the actors on television may imagine themselves like that character carrying out the aggressive actions of the character on television, and research evidence suggests that exposure to media aggression does indeed 'prime' other aggressive thoughts, evaluations, and even behaviors such that violence viewers report a greater willingness to use violence in interpersonal situations.

Only Rowell Huesmann's (1986; see also Huesmann, 1997) theoretical formulation of the social developmental model of violence effects offers a true reciprocal theoretical account of how viewers' interest in media violence, attention to such violence, and individual viewer characteristics may interact in a theory of media violence effects. Using ideas from social cognition theory he develops an elaborate cognitive mapping or script model. He argues that social behavior is controlled by 'programs' for behavior which are established during childhood. These 'programs' or 'scripts' are stored in memory and

are used as guides to social behavior and problem solving. Huesmann and Miller (1994, p. 161) submit that "a script suggests what events are to happen in the environment, how the person should behave in response to these events, and what the likely outcome to those behaviors would be." Violence from television is 'encoded' in the cognitive map of viewers, and subsequent viewing of television violence helps to maintain these aggressive thoughts, ideas, and behaviors. Over time such continuing attention to television violence can thus influence people's attitudes toward violence and their maintenance and elaboration of aggressive scripts.

This theory suggests that while viewing violence may not cause aggressive behavior, it certainly has an impact on the formation of cognitive scripts for mapping how to behave in response to a violent event and what the outcome is most likely to be. Television portrayals, then, are among the media and personal sources that provide the text for the script which is maintained and expanded upon by continued exposure to scripts of violence.

Huesmann has demonstrated that there are key factors which are particularly important in maintaining the television viewing–aggression relationship for children: the child's intellectual achievement level, social popularity, identification with television characters, belief in the realism of the TV violence, and the amount of fantasizing about aggression. According to Huesmann, a heavy diet of television violence sets into motion a sequence of processes, based on these personal and interpersonal factors, that results in many viewers becoming not only more aggressive but also developing increased interest in seeing more television violence.

It must be emphasized that all serious scholars of the impacts of media on violence are careful to note that media are not the only, nor perhaps among the most important, contributors to real-world violence. Violent behavior is a complex, multivariable problem, formed of many influences. Racism, poverty, drug abuse, child abuse, alcoholism, illiteracy, gangs, guns, mental illness, a decline in family cohesion, a lack of deterrents, the failure of positive role models, among others, all interact to affect antisocial behavior. As Huesmann has argued, aggression is a syndrome, an enduring pattern of behavior that can persist through childhood into adulthood. The impact of media violence appears strongest as a predictor of real-world antisocial behavior as one facet of a 'culture of violence.'

Types of Effects

As Potter (1999, Chap. 9) notes, media-violence effects fall into five categories – physiological, emotional, cognitive, attitudinal, and behavioral – and both immediate or short- and long-term effects have been studied. While some attention has focused on direct, short-term imitative or modeling effects (cf. Phillips, 1980, 1982, but see Hessler and Stipp, 1985), more attention and public policy concern has focused on the long-term impact of repeated exposure to violence. More generally, three overarching categories of effect receive most attention: learning of aggression, desensitization to real-world violence, and the cultivation of fear in repeated exposure to media violence (Wilson et al., 1997).

Clearly, not all violent depictions should be treated equally, nor all viewers. The (US) National Television Violence Study (Wilson et al., 1997) identified several contextual factors within a representation that may influence audience reactions to media violence which include the following.

The Nature of the Perpetrator

Where individuals perceive perpetrators of violence as attractive, as heroes, and/or as similar to themselves, the likelihood of stimulating attention (Bandura, 1986) and aggression (Paik and Comstock, 1994) increases.

The Nature of the Victim

While the commission of violence on an attractive character with which an audience member identifies might serve to inhibit aggressive behavior, its principal impact would seem to be in arousing fear among the audience members.

The Reason for the Violence

Wilson et al. (1997, p. 24) note that violence viewed as justified likely heightens aggression, while violence viewed as unjustified arouses fear. The impact of justification has been documented with fictional as well as realistic programming (Meyer, 1972), and with adult as well as child viewers (Liss et al., 1983). In fact, a recent meta-analysis of 217 media studies documents that a justified portrayal of violence can enhance aggressive behavior among viewers (Paik and Comstock, 1994).

The Presence of Weapons

A number of studies, including a meta-analysis of 56 published experiments (Carlson et al., 1990) have demonstrated that the presence of weapons, either pictorally or in the natural environment, can enhance aggression among subjects. While, for ethical reasons, the large majority of such research involves adult subjects, in at least one study (Frodi, 1975) the presence of weapons enhanced aggression among adolescents. 'Conventional' weapons such as guns and knives are more likely than unconventional means for priming the effect, social learning theory would suggest, because their use as a means of aggression are stored in memory (Berkowitz, 1990; Leyens and Parke, 1975).

The Extent and Graphicness of the Violence

A review (Wilson et al., 1997) for the National Television Violence Study suggested that more research is needed, but several tentative conclusions about extent and graphicness could be reached: (1) extensiveness of violence *within* media presentations should be associated with increased desensitization to violence, at least in the short- to medium-term; (2) graphicness of violence should be associated with increased cultivation of fear; (3) longitudinal studies clearly suggest that extensiveness of *viewing*violent media presentations heightens the likelihood of engaging in aggressive behavior.

The Degree of Realism of the Violence

In brief, realistic violence has been found to induce aggressive behavior, and to induce fear, more than violence believed to be

less realistic or more fantastic. An extremely important qualification deals with younger children, who may be unable to distinguish realistic from fantastic characters, behaviors, and situations. In one study, however, where *perceived realism* was manipulated for older children (9 – 11 in Feshbach, 1972; 10 – 13 in Atkin, 1983), those subjects who were led to believe that footage was realistic news were more likely subsequently to behave aggressively than those led to believe it was taken from an entertainment program.

Whether Violence is Rewarded or Punished

Rewarded violence is more likely to be imitated than violence which is punished. Significantly, and particularly for children (since, as we will show below, television programming most frequently presents violent actions that are neither rewarded nor punished), the absence of punishment may enhance imitation, even in the absence of explicit reward (Bandura, 1965; Walters and Parke, 1964). Paik and Comstock's meta-analysis (1994) suggests that rewarded violence stimulates aggression among both child and adult audiences. One study suggests that punishment of criminal violence decreases fear (Bryant et al., 1981).

Consequences of Violence

In general (and exceptions are noted in Wilson et al., 1997, p. 30), mediated depictions of violence which show either pain cues or other short- or longer-term negative effects or consequences of violence are likely to depress the learning of aggression. There is little research on the effects of pain cues or violence consequences on desensitization and the cultivation of fear.

Presence of Humor

As the National TV Violence Study review also noted, further research is needed here as well, but the present state of knowledge suggests, other things being equal, that violence coupled with humor is more likely to heighten aggression, and to increase desensitization, than violence without the presence of humor:

> Several mechanisms can be used to explain such a facilitative effect of humor on aggression. Humor might elevate a viewer's arousal level over that attained by violence alone, and increased arousal has been shown to facilitate aggression. … Humor could serve as a reinforcement or reward for violence, especially if the perpetrator is funny or admired or his or her wit. And humor may diminish the seriousness of the violence and therefore undermine the inhibiting effects of harm and pain cues in a scene. … However, we should underscore that our conclusion about the facilitative effect of humor on aggression is tentative until more systematic research … is undertaken (Wilson et al. 1997, p. 32).

Young Viewers

As noted, research indicates that certain factors may be processed differently by young viewers. First, children below about age 8 have more difficulty distinguishing reality from fantasy and often imitate superheros with magical powers such as the *Power Rangers* (Boyatzis et al., 1995). Second, young children may have difficulty connecting scenes and drawing inferences from the plot. Timing of punishments and rewards becomes important in this instance. In many programs, the crime or violent behavior may go unpunished until the end of the program. Young children may have difficulty connecting the ending punishment with the initial violent act and may, therefore, believe that the violence went unpunished (Wilson et al., 1997). Thus, learning of aggressive attitudes and behaviors from television varies by both the nature of the portrayals and the nature of the viewers. The presence of contextual factors in the portrayals which may inhibit young children's social learning of aggression decreases the negative consequences of such portrayals and should be encouraged. Not all violent portrayals are the same and the context of violence is clearly quite important. Similarly, young children, those under the age of 7 or 8, may be particularly susceptible to learning from exposure to television violence because of differences in how they make sense of television compared to adults.

The Media Environment

Television's role as the central mass medium in much of the world for the past half-century, and its ubiquity and ability to enter almost every home, often without parental supervision, has meant that more public and scholarly concern has focused on its contents than on any other medium's, and this concern has accompanied its diffusion into every corner of the earth.

Unfortunately, cumulative and comparative research on television's violent content is hampered by a lack of consistency in defining violence and especially defining the population and sampling frame in studies of television.

The most extensive single content study of US television was the 1994–97 National Television Violence Study (National Television Violence Study, 1997; Center for Communication and Social Policy, 1997, 1998). Examined were the 6 a.m.–11 p.m. contents of a multistage probability sample constructed sample week of programming on 23 network-station, independent-station, and basic-cable and premium-cable channels; thus about 8000 programs were analyzed over the 1994–95, 1995–96, and 1996–97 television 'seasons.' Certain programs, including 'hard news,' religious shows, sporting events, quiz shows, and educational shows, were sampled but not analyzed. About three-fifths of the remaining programs contained some visual violence, a figure that like most summary statistics remained stable over the 3 years of the study. In descending order, premium cable, basic cable, independent-station, broadcast network station, and public broadcast stations' programming were likely to contain violence. By content genre, in decreasing order, movies, dramas, children's shows, music videos, and reality-based and comedy programs were likely to contain violence. Violence was far more prevalent during prime-time than during daytime hours.

Of signal concern to the NTVS researchers was the *context* of televised violence; it was often glamorized (more than a quarter of all violence was perpetrated by 'good' or attractive characters,

and some 40% by characters with at least some good qualities); sanitized (about 7/8 of violent scenes show no blood and gore; almost half show no harm to victims of violence, although more than half of violent interactions show infliction of harm that would be lethal in 'real life,' and about half depict no pain cues in victims of violence); and unsanctioned (in a majority of scenes, violence perpetrators were neither rewarded nor punished ['punishment' was considered any noticeable sanction, including a perpetrator's oral expression of remorse], and among other scenes, rewards and punishments were about equally likely; in three-quarters of cases, characters perpetrating violence were either never punished, or were punished only at the program's conclusion). Moreover, only 3% of programs with violence had any antiviolence theme (Center for Communication and Social Policy, 1998, Chaps. 3–4). Potter (1999) has an extensive discussion of definitions of media violence and the results of content analyses from a variety of studies.

Media Violence and Public Policy

As noted, the consensus in the social scientific community regarding media violence is that it serves as a contributor to aggression in the real world, and virtually all public opinion surveys confirm that wider publics believe this as well. Nonetheless, such findings are 'controversial' in the media industries, and among a minority of academics (see, e.g. Fowles, 1999 and sources cited therein). In the United States in particular, since the 1950s the media industries – television in particular, but also recorded music, motion pictures, pictorial comic books, and video games – have responded to public and governmental outcries against violent content by promises to reform under self-regulation. Motion pictures, video-games, and recorded music all list 'ratings' for their products which suggest age-groups for which the industry self-regulatory groups think the content for these products is appropriate. The US Telecommunications Act of 1996 mandated that the television networks create a 'voluntary' ratings system or face creation of one by the federal government. The system the broadcast industry has created suggests appropriate age categories and levels of sex, language, and violence to allow consumers and parents to make program choices. The same act mandated a 'v-chip' in newly manufactured television sets to allow parents to screen or filter out violent programs. There is to date insufficient research to indicate whether and what sorts of parents and other viewers are using either the ratings or the v-chip technology to screen violence. However, experimental research by Cantor and her colleagues (Cantor and Nathanson, 1998, Cantor et al., 1997) suggests that young children may use aged-based ratings systems to shield themselves from violent content while for older children and adolescents, there may be a boomerang or 'forbidden fruit' effect whereby ratings *attract* them to more 'adult' violent or sexually explicit material. In the United States Congress, a moratorium on discussion of television violence is in effect, pending further information on the effects of ratings and the v-chip, but the legislature is focusing its attention on violent video-games, the target of significant public criticism in the wake of a number of firearms murders in public schools.

Conclusion

It is clear that where children and television violence are concerned, the question that remains is not whether media violence has an effect, but rather how important that effect is in comparison with other factors in bringing about the current level of crime in the United States and other industrialized nations. Future research should also aim to establish who precisely is most susceptible to media violence, and, most importantly, what sorts of intervention might help diminish its influence. At the same time, any interventions that help establish policies and practices to reduce the socially inappropriate ways of portraying violence and increase the socially responsible ways (such as using violence to assert antiviolence messages) should be encouraged as well. Long-term solutions to problems caused by violence in the real world, however, will require attention to a much wider variety of causal agents.

Abstract

Rather than approaching pervasive community violence (PCV) as a criminal justice problem requiring responses from police, judiciaries, and corrections, this article describes violence as a public health problem requiring responses from a variety of health and public policy perspectives. Here, we posit that community violence represents a toxin to the social ecology of communities that has radiating negative effects analogous to other environmental toxins. Drawing from local and global examples, we argue that assessing exposure to the toxic effects of PCV is a necessary first step in planning for interventions that mitigate negative impacts on individuals and communities. Notably, we argue that the burden of disease is highly varied and unpredictable, ranging from the most extreme internalizing outcomes (e.g., suicide) to extreme externalizing disorders (e.g., homicide). We propose a few approaches for measurement of the various fear circuitry disorders that may result as individual responses to PCV, as well as the use of community-based participatory research methods to develop evidence-based interventions to address PCV from a social justice and public policy perspective. The article concludes with a brief discussion of vulnerability and adaptation in communities exposed to pervasive violence, as well as factors related to resiliency and health-related quality of life.

Introduction

Just as the writing of this article neared completion, the following headline appeared in a local newspaper: *Short life marred by a milieu of violence* above an article reporting the fatal shooting of a 16-month-old boy by a gunman targeting the infant's father. The article described the infant's brief life and the *milieu* in which he was raised. This milieu was marked by nearly continuous and inescapable exposure to violence. His mother sought to escape from elements of this milieu by distancing herself from his abusive father; by reluctantly and infrequently taking her son outside; and by shielding him from angry and threatening neighbors. Despite his young age, she wondered if he would reach adulthood safe from harm.

As described below, such stories could be written any day in any week in many of the largest cities, both in the United States and elsewhere around the globe. Living under such conditions we describe as exposure to pervasive community violence (PCV) and liken its effects to other environmental toxins that can be fatal with direct contact and indirectly corrode physical, psychosocial, and emotional well-being of such ecologies. Not unlike the conditions within insurgencies and civil wars, PCV can have malignant effects on interpersonal trust within families and across neighborhoods; can isolate young and old alike in what they experience as the uncertain safety of their homes; and can undermine assumption about the future for oneself and especially, members of one's family that are male and minority.

Because of PCV, violence and the threat of violence are increasingly recognized as serious public health problems in the United States and globally. Violence and its aftermath leave no demographic entity unaffected. In the United States in 2009, 16 800 people were victims of homicide; an additional 37 000 took their life (http://www.cdc.gov/violenceprevention/). The incidence of violent deaths in the United States is alarming; its incidence across the globe, especially in war-torn areas is staggering!

These lost lives, however, represent merely a fraction of the impact of PCV exposure! We argue herein that PCV exposure cumulative impact is the creation of a sustained psychosocial environment as toxic to human health as many other forms of ecological toxins. These effects include not only physical injury and death following direct contact with violence but also deep-seated psychological and psychosocial 'bruises' which may interfere with health-promoting interpersonal connections; limit access and openness to intimacy; and through an increase in anticipatory and reactive violence, actually increase the ambient PCV level. PCV exposure may result in permanent physical and emotional scars. PCV settings also require the diversion of substantial public resources to provide health care, public safety (i.e., through police and other forms of security), and lost productivity. Violence also has the potential to erode communities by decreasing property values; disrupting social services; and infecting relationships among neighbors with suspicion, caution, and trepidation.

In 2002, the Centers for Disease Control and Prevention and the World Health Organization produced a startling joint report of the impact of violence worldwide (Krug et al., 2002). Globally, interpersonal violence accounts for more than 1.6 million deaths annually and is one of the leading causes of death for people between the ages of 15 and 44. Although more than 90% of violent deaths occur in low- and middle-income countries, affluent nations are not insulated from this toxin. In the United States, for example, the December 2012 mass shooting of educators and primary grade children at Sandy Hook Elementary School; of moviegoers in Aurora Colorado; and the bombings during the 2013 Boston marathon occurred in affluent communities. Each of these tragic events resulted in public discussions of gun control, mental illness, and acknowledgment of the US's culture of violence. Each also expanded the number of people who no longer feel secure in their homes, in their schools, and in public venues.

Despite such high-profile cases generating cries for change (but not necessarily actual change!) and increasing awareness

that PCV is present across the United States and the world, its impact on those exposed remains poorly understood. Thus, we argue in this article that PCV exposure has become a characteristic of the environments in which many children, adolescents, and adults (teachers, parents, and citizens) live, work, study, and play across the world. During the 1990s, measures to assess the nature and levels of PCV exposure were developed for youth ranging in age from preschool through adolescence. Findings from the resulting surveys across multiple settings (urban, suburban, and rural) confirmed that PCV exposure is a widespread and damaging phenomenon. As noted above, documented physical, emotional, and behavioral consequences support consideration of PCV as an environmental toxin with measurable negative effects, including increase in its ambient level. Thus, PCV has the potential to increase its pervasiveness within the very environments in which it is encountered and thus to gradually expand beyond its original borders to contaminate adjoining areas and beyond.

The need to assess PCV exposure in adults is argued as a necessary antecedent to the design and implementation of interventions to protect against exposure and mitigate its initial effects.

Many of the epidemiological studies reported herein were conducted in the United States; it is imperative that similar epidemiological work be undertaken globally. Far too much of the world's population currently lives in war-ravaged or threatened areas or have escaped from such settings only to find themselves in dangerous refugee settings. Far too many women and children experience the impacts of domestic, family, and relational violence, and far too many others witness both these forms of violence, and their physical and emotional consequences.

As work began to understand and measure PCV during the 1980s, many policy makers and social scientists viewed PCV as a problem limited to low-income neighborhoods trapped in struggles among gangs competing to sell and distribute illegal drugs, especially cocaine and crack cocaine. From this perspective, the challenge for communities was to locate and restrain perpetrators and respond to their victims. Less public were efforts to contain such turbulence within these neighborhoods and thereby avoid or limit contamination of outlying areas. Gradually, there was recognition that community violence may affect all segments of the population. Those fearing victimization feel a need to protect themselves; often with tragic consequences. As this article was being prepared, a middle-class teenager died because he mistakenly entered a home close in location and in appearance to his own. Confused by the combination of alcohol and fatigue, the youth entered the wrong home, encountered an anxious middle-class homeowner who fearing for his family's safety killed the intruder before ascertaining whether the perceived threat was confirmed as valid.

We hypothesize but have yet to confirm empirically that PCV impairs judgment in such instances resulting, as noted, in unnecessary and unintended acts of violence. Increasingly, across the world seemingly clear distinctions between victim and perpetrator seem to fade. Heightened exposure to violence directly or through media reports of its occurrence appears to increase acts of aggression in anticipation of violence from another. Effectively, the timing rather than the nature of an act may differentiate victim from victimizer. Consider the aforementioned accidental death of the teenage victim who entered the wrong home. Had the homeowner paused long enough to be sure of the threat, he and his family may have been the victims and the teenager, the perpetrator. Acting too swiftly may be as dangerous as acting too slowly in a PCV environment!

In such an environment, the sense of unease may seem permanent, the need for vigilance continuous, and suspicion of others a required attribute. That state may, in turn, disrupt sleep, upset vegetative functions, impair interpersonal relationships, and disable effective concentration on work and studies. Together, this constellation of 'fear circuitry disorders' (Andrews et al., 2009) representing a specific group of stress-induced and fear-based disorders are now identified in DSM-5 as a distinct classification as Stress-Induced and Fear Circuitry Disorders. This classification brings together diverse fields as neuroscience and community psychology and may lead to more refined treatments for these conditions based on a better understanding of the biological and environmental factors that contribute to their development. These disorders range from posttraumatic stress disorder, panic disorder and agoraphobia, social phobia, and specific phobias, and recent work suggests that they may be closely related in terms of brain pathophysiology. PCV, therefore, may negatively alter the essence of community life, broadly disrupt its functioning, and presumably thereby impair residents' general physical and emotional health.

The potential for such broad impact must be appreciated and respected *before* one can enlist communities to investigate PCV's nature and consequences. Investigators who do not appreciate that quality of the study depended on this aspect may be surprised by the reluctance of community leaders (e.g., school administrators, county health officer, and representatives of the mayor's office) to participate in its study. The leaders may deny the problem's extent or hesitate to make public the negative quality of their neighborhood or community. For them genuine partnerships require time-tested, abiding historical involvement and future commitment. Historical involvement enables disclosure and trust. Intimate aspects of a community are rarely shared with strangers. Assurance that the investigator will be there in the future (even after external funds are gone) is important, given community leaders' appreciation of the intransigence of social problems and the fickleness of social scientists.

Thus, from the outset it must be appreciated that to study and alter the nature and consequence of PCV requires a genuine and long-term partnership between communities and social scientists that is exemplified by Community-Based Participatory Research (CBPR). Roberts (2013) suggests that CBPR activities flow from the foundational principles of respect for persons, beneficence, and justice that were outlined in the Belmont Report (1979). Roberts (2013) insists that CBPR activities must always demonstrate a fundamental and deep regard for the dignity and autonomy of individuals who constitute a community by virtue of residing in a certain geographic location, having a shared racial, ethnic, or cultural identity: or living with a particular illness. Advances in biomedical ethics have invariably occurred very slowly, even glacially, and historically only after

public outrage at abuses such as were revealed at Nuremberg, Tuskegee, and other infamous projects and experiments.

What differentiates CBPR from traditional approaches to conducting research is the sharing of power and participation with communities from the very beginning of any project. CBPR is not conducted 'on' participants with particular characteristic or illnesses, or 'in' communities where they live, but rather it conducts research 'with' communities and stakeholders. That difference is essential! Shared decision-making and embracing an empowerment process (Rappaport, 1981) are the cornerstones of CBPR. When Rappaport argued for a social policy of empowerment rather than prevention, he described it as paradoxical because he recognized that only by recognizing and valuing the strengths in individuals, groups, and communities could programs be successfully implemented to address deficits, inequities, or illness. There is much to be learned from CBPR efforts that failed, and the behind-the-scenes narratives of what did not work and speculations as to why they failed, since those failure experiences are often as illustrative as are successes, and those types of lessons are often far more plentiful that than are the stories of success (Primavera and Brodsky, 2004).

Definition of Terms

In reviewing the growing PCV literature, the need for defining relevant terms becomes apparent. *Violence* refers to both acts and consequences of the *intentional* use or threat of use of force to cause injury, harm, or death to another. The qualifier 'intentional' excludes unintended or accidental acts and consequences. Determining intent represents an as yet unresolved methodological challenge. For PCV, the *consequences of violent acts* refer to the rippling health and mental health effects experienced by: (1) individuals directly victimized by an act or threat of violence; (2) individuals indirectly victimized as a bystander, witness, acquaintance, or loved one of a direct victim; and (3) individuals indirectly victimized by their awareness of, and anxiety about, the occurrence of acts or threats of violence. *Community violence* locates the acts and their consequences in a geographic setting (e.g., a neighborhood or a school), an identifiable social grouping (e.g., a grade cohort, a gang, a nuclear or extended family), or both. *PCV* refers to the chronic and widespread occurrence of acts or threats of violence within such settings or social groups.

Thus, PCV exists when *substantial* acts and consequences of violence are encountered across *multiple* settings and circumstances over *extended* time. To investigate PCV systematically, the qualifiers 'substantial,' 'multiple,' and 'extended' must be operationally defined and rigorously measured. Information must be gathered about a community's rate of violent acts and about rates of individual encounters with violent acts. For methodological and political reasons, PCV measures vary in their consideration of violence occurring within or outside of the home. The majority of such measures limit their focus to outside encounters. Yet, by definition, PCV implies cross-setting exposure. At its most extreme, PCV represents the absence of any sanctuary or setting in which relief and a sense of safety is possible. Thus, the most serious impacts on physical and psychological health are likely to be observed in those exposed at home, at work or school, and en route between the two.

In a series of papers and articles, Lorion and colleagues proposed consideration of *PCV as an environmental contaminant* with measurable effects on health and mental health (Cooley-Quille and Lorion, 1999; Lorion, 1998, 1999, 2001a,b; Lorion et al., 1998; Lorion and Saltzman, 1993) From that perspective, PCV contaminates settings and thereby the actions and interactions of at least some inhabitants. *Contamination* refers to the corrosive or pathogenic effect of PCV exposure on community climate. Slowly investigators are documenting PCV's negative effects on: (1) individual assumptions about the threatening quality of others, (2) the need to limit one's contact with others, and (3) the urgency of responding aggressively to actual or anticipated attacks. This ecological contamination appears to vary in its pace as well as intensity across individuals, situations, and settings. Understanding the determinants and mechanisms of such patterns and their malleability within and across individuals should inform the design of interventions to limit PCV exposure and reduce its consequences.

Measuring PCV

As reflected in this section of the article, attention has shifted in the past decade from continued examination of PCV as a significant ecological influence on emotional and physical behavior in spite of its continued persistence and, we believe, expanding toxicity. Ideally, reviewing past work will have a heuristic influence on renewing interest in understanding and preventively controlling the PCV's repercussions. Investigation of PCV's environmental influence requires the availability of measures to estimate its presence and to confirm its impacts. Applying a common measurement approach across diverse populations and settings, Richters and associates (Lorion and Saltzman, 1993; Martinez and Richters, 1993; Osofsky et al., 1993; Richters and Martinez, 1993) scientifically documented the extent of children's exposure to violence. They also provided early evidence of the relationship between PCV exposure and children's emotional and behavioral functioning. Subsequent investigations of such relationships (e.g., Hill and Madhere, 1996; Singer et al., 1995) confirmed the seriousness of such links.

Measures of exposure to community violence share many similarities with the *Survey of Children's Exposure to Community Violence* (Richters and Saltzman, 1990). Instructed explicitly *not* to include media exposure (i.e., what was seen or heard about on radio, television, or in movies), respondents indicate along a five-point Likert scale (from 0 = *never* to 4 = *a lot of the time*) how often they have been victimized by, heard about, or witnessed violent events or related activities (e.g., shooting, stabbing, mugging, seeing a dead body). For each instance of reported exposure, respondents provide information about: (1) where the exposure occurred (i.e., in or near school, in or near home, in the neighborhood); (2) who perpetrated the violence (e.g., a stranger, a family member); (3) who, if not the respondent, was victimized (e.g., a stranger, a family member); and (4) when the incident occurred (e.g., 1 week ago, 5 years ago).

Variations of this measure were applied by Martinez and Richters (1993) and Osofsky et al. (1993) in studies of mothers of elementary graders and by Richters and Martinez (1993) and Saltzman (1992) in their studies of fifth and sixth graders. A cartoon-based version of this measure was designed by Richters and Martinez (i.e., Things I Have Seen and Heard, 1990) to assess PCV exposure in primary graders. Test–retest reliability was the most acceptable $r = 0.81$. A second cartoon-based measure, Levonn, assessed distress symptoms associated with exposure (Richters et al., 1990). Subsequently, Fox and Leavitt (1995) developed the Violence Exposure Scale for Children (VEX-R) as a cartoon-based measure of PCV exposure in children from preschool through the elementary grades. Using this measure, Shahinfar et al. (2000) documented PCV's impact on preschoolers. The negative behavioral consequences of such exposure were confirmed in a sample of Israeli elementary school children by Raviv et al. (2001).

A further variation of the Richters and Saltzman (1990) measure was applied by Saltzman (1995) to examine PCV exposure's link to adolescent involvement in antisocial and delinquent behaviors. Building on these variations, Singer et al. (1995) designed the Recent Exposure to Physical Violence and the Past Exposure to Violence surveys to obtain adolescent reports of exposure during the prior 12 months or 'while growing up, not including the past year,' respectively. The acts of violence surveyed by Singer et al. included threats, slapping, hitting, punching, beatings, knife attacks, and shootings. Separate reports for each (other than knife attacks and shootings) were obtained for home, school, and neighborhood. Respondents were also asked how often they had witnessed someone else victimized at each of the aforementioned sites. Two additional items inquired about respondents' having been 'made to do a sexual act' or having witnessed someone else 'being made to do a sexual act.' Overall, measurement efforts to date support the conclusion that psychometrically acceptable reports of PCV exposure can be obtained from youth ranging in age from preschoolers to adolescents.

In addition to the above work, Jenkins and associates (Bell et al., 1988; Jenkins and Thompson, 1986) designed and conducted qualitative studies of African-American children's encounters with violence. Results from four studies are summarized in Bell and Jenkins (1993). Using related measures, Jenkins and colleagues obtained information about youth's exposure in terms of: (1) knowing someone who was a victim of violence; (2) having witnessed violent events *in real life*; (3) having been a victim of a violent incident; and (4) having perpetrated a violent act. Comparable to the work mentioned above, information about such forms of exposure was obtained from students enrolled in grades 2 through 12.

Although not a universal experience, victimization occurs at levels approaching 50% for threats and 40% for forced entry into their home. Indirect victimization (e.g., being a witness to a violent act) levels were consistently higher for incidents ranging from drug use to shootings, stabbings, and muggings. Reports of seeing a dead body in the neighborhood ranged from 24 to 40%. Using an extension of the Richters and Saltzman measure, Singer and colleagues (Singer et al., 1995; Song et al., 1998) validated these reports in their surveys of high-school students ($N = 3735$). As expected, considerable variability is present across settings. Nevertheless, levels of victimization and witnessing (both at home and in school) justify recognition of PCV as a major environmental contaminant. Apfel and Simon's (1996) description of communal violence as referring to settings in 'which every child has witnessed or expects to witness violence and has been or expects to be violated' (pp. 4–5), seems to apply to many of the nation's neighborhoods and schools.

Increasingly, evidence suggests that there are important associations between perceptions of neighborhood problems and health-related quality of life (HRQL). The perceptions of the same neighborhood are often quite divergent between different people living in the same place (Dahl et al., 2010). Perceptions of neighborhood problems are often found to be negatively predictive of psychological, social, and environmental HRQL. This suggests that the various aspects of well-being may be influenced as much by perceptions of neighborhood problems as actual neighborhood characteristics (Erin et al., 2012).

Assessing PCV's Health Impact

Older studies also report on PCV's toxicity. Saltzman (1992), for example, observed significantly higher levels of generalized emotional distress in PCV-exposed fifth and sixth graders. This pattern is also reported by Richters and Martinez (1993), Martinez and Richters (1993), Osofsky et al. (1993), and Bell and Jenkins (1993). Across these studies of preadolescents, PCV exposure relates positively to affective and vegetative signs of depression and indices of stress-related disorders. With both preadolescents and adolescents, Singer et al. (1994) linked PCV exposure and increased aggression, conduct disorder, running away, and lowering of self-esteem and social competence. Support for the link between PCV exposure and involvement in violent acts is reported by Saltzman (1995). In Saltzman's study, PCV exposure significantly related to adolescent involvement in antisocial and violent acts independent of peer, familial, and other recognized predictors of aggression during that developmental period. Rubinetti (1996) linked PCV exposure and violent activity most strongly in youth with decreased empathy, hopelessness, and lowered self-esteem. Provocatively, Song et al.'s (1998) findings suggest that indirect victims are more likely than direct victims to aggress *in anticipation of* violent acts. Although further study is needed, PCV may: (1) create interpersonal distance among the residents of an affected setting; (2) desensitize them to the consequences of violence on others; and (3) heighten the perceived need to defend oneself against assault. Overall, there appears to be substantial evidence that heightened exposure to PCV increases the likelihood that one will engage in violence. In turn, the resulting acts of violence increase levels of PCV exposure, providing a mechanism for a recursive, continuing cycle.

Two other studies (Cooley-Quille and Lorion, 1999; Scarpa et al., 2000) reinforce the physical impacts of PCV exposure. Each study found physiological concomitants of PCV exposure, including increased heart rate, respiration, and

cortisol levels, long-established indices of heightened stress, and arousal. Cooley-Quille and Lorion (1999) also reported preliminary evidence of a link between PCV and sleep disorders. Anecdotal reports from youth living in PCV-heightened neighborhoods report difficulty falling asleep, repeatedly waking up in response to gunshots, loud noises, and police activity and, generally, only rarely sleeping throughout the night. If these reports are confirmed along with further information about the vegetative effects of PCV exposure, new understandings may emerge which change existing assumptions about the lack of impulse control and academic failure, often associated with urban poverty, from attributions about personal failure to questions about environmental toxicity. Thus, although examination of the physiological consequences of living or working within settings characterized by high PCV levels is just beginning, preliminary results suggest that these impacts are real, extensive, and potential triggers for further pathogenesis across multiple parameters of functioning.

Such findings support the hypothesized toxicity of PCV exposure, which appears to impair cognitive, emotional, behavioral, and biological functioning simultaneously, sequentially, or synergistically. As yet unexamined systematically, however, is the breadth of these 'PCV-consequences' (assuming they are causally linked) within settings and communities. In essence, we have yet to study how the toxin spreads and the transmission routes by which the occurrence of violent events (presumably their nature, frequency, and intensity would influence the spread of effects) contaminates the environment. Longitudinal information is necessary to causally link exposure and its observed concomitants. It is also necessary to determine at what point interventions can be introduced to protect against or, if necessary, to treat such effects.

It should be recognized that what is presently known about PCV relates almost entirely to school-aged youth. We know little about the effect of maternal PCV exposure on neonates, of exposure on toddlers and preschoolers, and even less about the nature, extent, and consequences of exposure on adults including on senior adults for whom PCV may lead them to limit their movements outside of their homes and thus this contact with others. What of the parents, grandparents, and others who live in such neighborhoods? Within schools, what of the staff and teachers who may live in such neighborhoods, travel through such neighborhoods, or hear the tales of their students?

Work reported to date pays little attention to these members of exposed communities, except perhaps to suggest that they could buffer youth against the impacts of PCV. Whether we can assume the capacity of exposed adults to do so merits careful examination!

We must therefore examine exposure to PCV across the entirety of a community's population and settings. Anecdotal reports, informal focus groups, and clinical encounters suggest that exposure reduces the quality of teachers' instructional effectiveness, capacity to apply classroom management strategies, and availability to students before or after the school day. Reasonably, one might expect that PCV similarly disrupts parent–child, parent–teacher, and teacher–teacher interactions. As reported above, Song et al. (1998) found a significant link between indirect exposure and anticipatory aggression. Ambiguous interpersonal cues may be interpreted by youth (and perhaps adults?) as threatening, leading to what is assumed by the perceiver as a defensive act. Presumably (although we do not really know), when self-defense seems unlikely to succeed, ambiguity leads to retreat, avoidance, or perhaps acquiescence with stated or unstated demands.

If this explanation of Singer's finding is valid, would it not extend to adult interactions within and across generations? Might it not explain, at least in part, what from the outside appears as hypersensitivity to insult or disrespect, the immediacy with which one asserts one's right, or the reluctance to give way, lest courtesy be mistaken for weakness or fear? Might it not explain urban parents' use of physical discipline or its reverse, that is, seeming inability or unwillingness to control their children's behavior? What of neighborhoods in which the elderly limit, and the young have limited, time outside of the home because of concerns about danger and vulnerability? Would not isolated streets facilitate violence with immunity? Would not the biological concomitants related to stress, sleep deprivation, and concentration impair adults' (be they teachers, storekeepers, bus drivers, or elderly neighbors) capacity to interact comfortably with each other and to neutralize or at least dilute PCV's toxicity and thereby protect youth? To ignore the status of adults in such settings implies that they are unaffected by PCV or other community toxins.

Albeit at levels of concern, PCV is linked to increased but not universal pathology. Not only does a majority of those so exposed not manifest pathology, but most residents do not report exposure. PCV exposure appears to relate not only to the occurrences of violent acts, but also to awareness of and sensitivity to those occurrences. Somehow, many exposed are seemingly unaware of that and, potentially, for them there is some bliss in ignorance. The individual and ecological factors that determine sensitivity remain to be investigated. That such differences exist, however, argues for attending to issues of adaptation, coping, and wellness. As noted recently:

> By implication it seems reasonable to view wellness as representing the outcome of normative developmental processes, in programming terms, as the default option. In the absence of that relatively rare combination of individual and situational circumstances, individual development appears to proceed within socially expected and appropriate boundaries reflecting the general capacity to adapt to situational demands and cope with stressful events. Just as canalization accounts for the limits within which genetic processes emerge within species (Gottlieb, 1992), an analogous process may account for the human capacity to adapt to a multitude of settings and circumstances, and to cope with seemingly debilitating and pathogenic stressors.
>
> (Lorion, 2000: pp. 13–14)

If wellness, adaptation, and adjustment represent the default option in human development, and individuals, families, neighborhoods, schools, and communities in general cope with PCV, economic (dis)advantage, familial instability, critical life events, inadequate school budgets, and so on (the length of one's list merely underscores the point), understanding those mechanisms may inform the design of interventions to protect those who cannot cope. Answers to questions about how to optimize development and coping

must be out there, in the homes, the schools, the classrooms, and the neighborhoods. To find those answers, we in the social sciences must enter the communities to observe, inquire, and learn. I propose we go not as experts bringing esoteric knowledge, but as students and collaborators, hopefully bringing tools and perspectives whose utility will be determined relative to what already exists, and what can be sustained over time and across levels of resources.

Abstract

Homeless people are sometimes the perpetrators and quite often the victims of crime and violence. This article reviews the available research on this topic, focusing mainly on studies conducted in the United States. Homeless teens, women, the mentally ill, and the substance-abusive are shown to be especially high-risk subpopulations. Random acts of violence committed against homeless people are evidently on the rise, both in the United States and around the world. Around the world, many communities have responded to the rise in homelessness by criminalizing homeless behaviors. Unfortunately these measures do not assist people in exiting homelessness.

In popular thinking, homelessness and crime are tightly interwoven (Amster, 2008). Homeless shelters and other locales frequented by homeless people are routinely avoided because they are perceived as crime hot spots, and homeless people themselves are routinely avoided because of their real or imagined criminal potential (Snow et al., 1989). Homeless individuals are often seen as irresponsible and deviant, leading to a public perception that equates homelessness and crime (Barak, 2002). While the media and many policies targeting homeless people focus on the perpetration of crime by homeless people, scholarly research has tended to focus on the victimization of homeless people (Crawford et al., 2011).

The Homeless as Perpetrators of Violence

Most of what we know about criminal perpetration by homeless people comes from studies examining previous arrest and prison experience. In a study of 767 homeless people in Austin Texas, Snow et al. (1989) found that the typical arrest of a homeless person was for a minor offense such as vagrancy or shoplifting. Out of their total sample, 32% had been arrested at least once, but the vast majority of those arrests were for nonviolent crimes. While homeless men are no more likely than the general male population to commit violent crimes, they are arrested more frequently for nonviolent crimes (Snow et al., 1989). A national survey of homeless providers and homeless clients in the United States found that 49% had been incarcerated for five or more days in jail, but only 18% had spent time in a federal prison (Burt et al., 1999). The authors note that, "some of these jail experiences may have been a direct result of their homelessness (i.e., the charges might be for behaviors that are difficult to avoid if one is homeless, such as loitering)" (Burt et al., 1999: 25). Kushel et al. (2005) found that among their sample of ~1500 homeless people, nearly a quarter had spent time in prison. Drug use (specifically cocaine, methamphetamine, and heroin) as well as mental illness were positively correlated with past prison experience. In the United Kingdom, Fitzpatrick et al. (2013) conducted a statistically generalizable survey of homeless people and found that 46% had been incarcerated at some point in their lives. However, detailed information on the nature of their incarceration was not available and, thus, the nature of the crimes committed is not known.

Both mental illness and substance abuse among homeless people increase the likelihood that they will be arrested and incarcerated. In a study of homeless adults, 20% of those with substance abuse issues had been arrested in the past year compared to 10% of those that did not have a substance abuse problem (O'Toole et al., 2004). McGuire and Rosenheck (2004) found in their study of 7000 homeless people with serious mental illness that two-thirds had histories of incarceration. However, of these about half had spent a total of six months or less of their lives incarcerated. Among those with more extensive incarceration histories, substance abuse was a positive correlate, illustrating the relationship between mental illness and substance abuse.

In the United States, there are well-established links between mental illness, incarceration, and homelessness (DeLisi, 2000; Ditton, 1999; Snow et al., 1989). Deinstitutionalization of the mentally ill in the United States began in 1955; thus, by 1980 or so (usually taken as the onset of the large upsurge of homelessness that happened in American and cities abroad), most persons destined to be deinstitutionalized already had been. The proper concern for the past two decades has, therefore, been not with deinstitutionalized but rather with the 'never institutionalized,' namely, mentally ill homeless people who had never been brought into a system of care. A related and even more pressing concern has been with the 'trans-institutionalized'; that is, those who might have been in mental hospitals in years past but are now in prisons and jails instead (Raphael and Stoll, 2013). Many homeless mentally ill people spend a great deal of time incarcerated; indeed, Torrey et al. (2010) conclude that there are more mentally ill people in jails and prisons than in psychiatric hospitals. Similarly, Markowitz (2006) found that in the United States, increased mental health and psychiatric hospital capacity was correlated with lower levels of homelessness. Most homeless people with mental illness problems in the United States find that there is nowhere to go for help. These individuals are often on the streets, increasing the likelihood of arrest and incarceration.

Among homeless youth, less is known about criminal perpetration. However, in the research that has been done, victimization and perpetration are both salient parts of a typical homeless youth's life (Crawford et al., 2011). One of the first studies examining criminal perpetration among homeless youths found that nearly 1 in 6 of the Los Angeles area youths in their sample had attacked someone with

a weapon while being on the streets, although this percentage was much lower than the rates of victimization these youths experienced (Kipke et al., 1997). In the Crawford et al. study, homeless youth who were female, nonminority, and heterosexual were less likely to engage in violence than their opposites; alcohol and drug-abusers were more likely to engage in violence, a common finding (Chen et al., 2006; Kipke et al., 1997). Moreover, increased time on the streets is positively correlated to rates of criminal perpetration (Whitbeck and Hoyt, 1999).

Most studies of violence perpetration among the homeless depict it as relatively minor and benign and the crimes they commit largely as survival behaviors, and not predatory criminality. While it is clear that the homeless are responsible for some crime and violence, it is yet to be established that the crime and violence they commit is any more common or more serious than that perpetrated by equally impoverished but housed individuals.

The Homeless as Victims of Violence

Most research examining homelessness and violence focuses on the victimization of homeless people and finds an association between homelessness and criminal victimization (Lee and Schreck, 2005; Thrane et al., 2006; Whitbeck and Simons, 1990). Even when compared to similar housed counterparts, homeless people report higher levels of victimization (Lee and Schreck, 2005), often by wide margins. It is nearly axiomatic that life on the streets or in the shelters exposes homeless people to high crime risks, and while the reward for victimizing a homeless person may be small, they are exceedingly easy targets, especially if they are also substance abusive, mentally ill, or both.

Violence as a Precursor to Homelessness

Victimization is both a cause and consequence of homelessness. Many studies have found an association between adult experiences of homelessness and childhood experiences of abuse and neglect (Mayock and Sheridan, 2012; McIntyre and Widom, 2011; Paradise and Cauce, 2002; Thrane et al., 2006) and repeated bullying (Bouffard and Koeppel, 2012). In a study of homeless adults in the United Kingdom, 22% reported being victims of physical abuse while 16% reported being victims of sexual abuse during their childhood (Fitzpatrick et al., 2013). Not only does the experience of childhood abuse and neglect increase the likelihood that people will become homeless, it also increases the likelihood that adult homeless people will experience victimization (Lee and Schreck, 2005; McIntyre and Widom, 2011; Jasinski et al., 2010).

Homeless Youth

Like homeless adults, homeless youths report higher rates of child abuse and neglect as compared to nonhomeless youths (Stoltz et al., 2007). Violence at home is, for many youths, the reason they become homeless in the first place. Oftentimes, they leave of their own volition (sometimes fleeing domestic situations so abusive that life on the streets becomes the preferred alternative) while other times they are kicked out. In a survey of homeless youth aged 13–17 years in Australia, 45% had experienced violence at home prior to becoming homeless (Australian Institute of Health and Welfare, 2008).

Homeless Women

Studies of victimization of homeless people have consistently found that homeless women are more likely to be victims of violence, particularly sexual assault and rape, as compared to homeless men (Evans and Forsyth, 2004; Kim et al., 2010; Kushel et al., 2003; Lee and Schreck, 2005). While homeless, the lack of suitable and stable shelter increases the likelihood that a woman will be a victim of violence, and here too, this is particularly true if substance abuse or mental illness is also part of the picture.

A great deal of research concerns the role of violence in the lives of homeless women. While violence is unfortunately a salient part of homelessness for many people, this is particularly true among women. For many homeless women, victimization begins at home in childhood and continues as an adult experiencing homelessness. Across numerous studies, homeless women who report having been abused as a child also report higher rates of violent victimization as an adult. Research examining why this correlation exists has not been conclusive. Some of the cited relevant factors include a lack of skill in developing healthy and safe relationships, a lack of knowledge of what constitutes a healthy relationship, the inability to recognize warning signs of an abusive relationship, general low self-esteem, and depression (see Jasinski et al., 2010; for an overview of relevant literature).

Domestic violence is a main cause of homelessness among women. In the US data reported by Jasinski et al. (2010), approximately three-quarters of homeless women reported histories of domestic violence and about one in four cited intimate partner abuse as a or the main reason for their current homelessness. Other studies have suggested that as much as half of all homelessness among women is precipitated by domestic violence and abuse.

While the majority of research in this area comes from the United States, the connection between violence and homeless women is not unique to the United States. In 2007, half of the homeless women in Australia seeking homeless services cited violence as the cause of their homeless status (Homelessness Taskforce, 2008). In a study of 60 homeless women in Ireland, 72% reported being victimized as children and two-thirds reported experiencing intimate partner violence as an adult (Mayock and Sheridan, 2012).

Victimization While Homeless

Homeless people have been victims of physical attacks and even murder around the globe including in the United States (National Coalition for the Homeless, 2012) and Japan (Fujii and Tamaki, 2003). Among the homeless adult population, those sleeping rough or unsheltered and those that are mentally ill (Dennis and Steadman, 1991) are particularly vulnerable to violent attacks. A pertinent CNN story of 20

February 2007 referred to this as 'sport killing' and reported that "Teen 'sport killings' of homeless [are] on the rise."

Since 1999, the National Coalition for the Homeless (NCH) has issued an annual report on attacks against homeless people in the United States. Through the end of 2011, the NCH has documented 1289 attacks of violence against homeless persons perpetrated by housed individuals in the United States, including 339 murders (National Coalition for the Homeless, 2012). Among these documented attacks, the most common perpetrator is a young man (under the age of 30 years) while the typical victim is an older man (aged 40–60 years). The NCH focuses on attacks on homeless people perpetrated by housed people. Information about violence perpetrated against homeless people by other homeless people is extremely scarce.

In regard to homeless youths, one of the most commonly found salient factors is the history of child abuse. Among homeless youth this has been associated with greater levels of victimization as adults in many studies (Melander and Tyler, 2010; Tyler et al., 2001; Tyler and Melander, 2013; Whitbeck et al., 2001). Among the homeless youth population, those that identify as gay, lesbian, or bisexual seem to be at disproportionate risk of victimization as compared to their heterosexual counterparts (Tyler, 2008).

In the United States, several states have responded to attacks against homeless people by adding housing status to their state hate-crime statutes. Despite several attempts, housing status is not included in the United States federal hate-crime definition. Likewise, while there have been widely publicized attacks against homeless persons in the United Kingdom, to date homeless people are not protected under the UK hate-crime law (Garland, 2012). While hate crimes of any sort are relatively rare occurrences, many argue that homeless people are particularly vulnerable and that these occurrences serve to further delineate between the value and rights of the housed versus those of the unhoused (Wachholz, 2009).

Criminalization of Homelessness as a Policy Response

Across the United States, Europe, and elsewhere, the response to the issue of homelessness has often been to criminalize behaviors associated with homeless people (for the US case, see Donley and Wright, 2008; for a case study in Europe, see Bence and Udvarhelyi, 2013; for the Asian case, see e.g., Wardhaugh, 2012). These criminalization measures are not designed to address the causes of homelessness but rather serve as measures to remove homeless people from public places. Criminalization tactics come in many forms and vary across jurisdictions. Some of the more common measures include the enactment of law targeting homeless-related behaviors and 'street sweeps,' where homeless people are forcibly removed from certain areas within cities.

Law enforcement has attempted to protect citizens, business owners, and public spaces by criminalizing unavoidable, yet undesirable actions, but this approach may be ineffective and counterproductive. "Police, attorneys, judges, and other actors in the criminal justice system … see panhandling as a minor offense the prosecution of which consumes valuable time, leaves root causes intact, and fails to deter reoccurrence" (Lee and Farrell, 2003: 318). Deterrence cannot have an effect when the person sometimes has no other choice but to commit a crime for basic subsistence (Davis, 1992). The NLCHP (2011) concurs that the criminalization of homelessness only has temporary effects on homeless criminal activity, jailing them for a short period of time then releasing them with no choice but to commit the same 'subsistence crimes' again.

Los Angeles is an example of a major American city that has used aggressive policing as a response to homelessness. This effort is also one of the few that was subsequently examined in terms of cost and effectiveness. The Safer Cities Initiative carried out in the notorious LA Skid Row area issued citations at 50 to 70 times the average rate and only 21 of the 1346 nondrug arrests in the area were for violent crimes (Blasi, 2007). Many individuals were cited for small crimes such as sitting on the sidewalk or throwing cigarettes on the ground. Homeless individuals often do not have the ability to pay the associated fines, would consequently be arrested, and released back onto the street with no other options. In just under a year of the Safer City Initiative, 24 individuals were arrested 201 times at an estimated cost of 3.6 million US dollars. The police officers used to carry out this initiative cost the city of Los Angeles an additional 6 million dollars. In the end, there was a decrease in the number of homeless individuals in Skid Row but an increase in the number of homeless individuals in surrounding areas. Thus, these measures did not decrease the number of homeless people but rather resulted in nothing more than some relocation of the homeless to other areas.

Budapest is an example of a European city that has attempted to end homelessness by outlawing it. Among the measures adopted by the Hungarians is a federal law allowing local municipalities to ban the 'inadequate use' of public spaces; in Budapest, this became a prohibition on the use of public space for 'habitual residence' or storage of one's belongings (Bence and Udvarhelyi, 2013). In the same vein, various districts in Budapest have been declared 'homeless-free zones,' and there has been a recent Constitutional amendment guaranteeing the right of local governments to criminalize 'habitual residence' in places not intended for human habitation.

Of all the behaviors associated with homelessness in the public mind, panhandling is evidently one of the most offensive (Lee and Farrell, 2003). As a result, this behavior has been a main target of effort to 'clean up the streets.' However, "contrary to common belief, panhandlers and homeless people are not necessarily one and the same. Many studies have found that only a small percentage of homeless people panhandle, and only a small percentage of panhandlers are homeless" (Scott, 2002). Although exact numbers are unavailable, estimates of the percentage of homeless people that engage in panhandling range from 5 to 40% (Lee and Farrell, 2003). Moreover, many panhandlers are not homeless. Goldstein (1993) found in his research in New Haven, Connecticut that only one-third of panhandlers were actually homeless. Nevertheless, panhandling and homelessness are intimately linked in public thinking.

The criminalization of homelessness is an international concern as research has pointed to an increase in privatization of public spaces, anti-homeless legislation, and practices of forced displacement in many countries including Canada,

United Kingdom, Germany, Hungary, Australia, New Zealand, the Netherlands, and Japan, as well as the United States.

China too has undergone major changes in the way it responds to homeless people over the past 15 years. Centers that used to be places where homeless people were incarcerated for activities such as begging have been converted into homeless aid centers. While many hail this change as a major improvement, criminalization persists. Anti-begging laws are common and beggars are portrayed in the media as criminals (Kennett and Mizuuchi, 2010).

Conclusion and Future Research

The criminalization of homelessness in the United States has been the subject of numerous lawsuits that argue certain ordinances infringe on citizens' freedom of speech and movement as well as freedom from unreasonable search and seizure, cruel and unusual punishment, discrimination, and forced evictions. The Supreme Court has ruled against the vagueness of some anti-homeless legislation (*Papichristou vs City of Jacksonville*). It has also been ruled that certain anti-homeless legislation is unconstitutional if it prohibits basic 'life-sustaining activities' and if alternatives do not exist. In the absence of these conditions, people cannot be prosecuted for things such as sleeping in the park or relieving themselves in public (*Pottinger vs City of Miami*, *Jones vs City of Los Angeles*). The United States Congress passed the Helping Families Save their Homes Act of 2009 requiring the development of alternative solutions to criminalizing homelessness. Anti-panhandling initiatives have been more successful. Although general panhandling is protected under the First Amendment in the United States, aggressive panhandling has been legally banned in communities across the country (Wright and Donley, 2011).

While this is not the place to review all the root causes of homelessness, it can be said that homelessness results when there are more low-income people than there are low-income housing units. At its base, in other words, homelessness results from inadequate incomes and inadequate supplies of affordable housing. Being homeless places people at high risk for criminal victimization, and this often puts these same people in positions where petty criminality is nearly required for daily survival. Criminalizing homelessness by criminalizing the behaviors associated with homeless does nothing to address root causes; this attacks the symptoms of the problem rather than the problem itself. No city in the world has eliminated homelessness via criminalization, although many have tried.

Future studies should examine the potential impact of programs designed to address root causes of homelessness as opposed to criminalizing homelessness-related behaviors. In addition, it is important to better understand levels of criminality among homeless people. While some studies have been done to date, typically these must rely on arrest data, self-reports among sheltered homeless individuals, or analysis of individual cases. A great deal of research today examines reintegration of individuals exiting criminal justice institutions and reentering communities. The reintegration of homeless individuals presents unique challenges and, thus, research that focuses on these issues would be particularly important.

Abstract

History of violence is not a field of its own in historiography, but it participates in broader debates. These debates are dealing with long-term development and questions whether violent means in public and private life are regressing or expanding. They are part of the history of social movements, criminality, terrorism, genocides, and ethnic cleansing. Political, social, and cultural history approaches are mobilized in these studies.

Violence in its various forms has been an aspect of historical writing since Thucydides, but to this day there is no independent specialty in historical research on violence. The history of violence is thus written as part of military and war history, of research on revolution and protest, and of the history of gender and the body. In Europe and elsewhere, it cuts across the institutional and disciplinary logic of the study of history. This lack of independence has two consequences for historical research on violence. First, it is always interdisciplinary and includes approaches proper to political science and social history, as well as issues of cultural history. Second, it cannot look back on a unified development, but on disparate traditions in the individual disciplines. While revolutionary violence, for example, is discussed primarily in the context of the French Revolution, research on social protest has developed under the influence of 1950s Anglo-American social history and of the reactions to the 1960s urban riots in the US. The historiography of research on violence is thus many stranded and international.

Definitions of Violence

The definitions of violence are as varied as its manifestations. The term itself takes on disparate coloring in the context of each respective national language. English, French, and Italian reflect the Latin and emphasize the injuries caused by violence and its violation of corporal integrity. By comparison, the German term *Gewalt* is less negatively charged, also being used as a synonym for 'power' or *pouvoir*. Only its extension *Gewalttatigkeit* captures the injurious character of the Anglo-American term. In English, the term *force* is designing legitime violence. In German, the legitimation of violence means must use the generic term *Gewalt*. A comparative study of the historical development and significance of terms is a desideratum for research. The spectrum of scholarly definitions of violence is broad. The distinctions between direct and indirect, collective and individual, legitimate and illegitimate, concrete and structural, physical and psychological, and manifest and symbolic violence reflect varying accents in the discussion. Depending on the definition, the focus can be on the manifestations, the justifications, or the effects of violence. The term has been specified further in accordance with its intended use for qualitative or quantitative studies. Modern research on protest for instance sees collective violence when at least 20 persons take part in acts in which persons or objects are damaged.

In the current discussion among historians, violence is widely understood as injury to people's physical integrity, caused by various historical actors in various contexts. Here, violence is not seen as an anthropological constant, nor as a universal historical trait held in common, but tied to the actions of specific groups and conditions that are subject to change in various national societies and epochs. The German sociologist Heinrich Popitz has advanced this view (Popitz, 1986). He sees violence as "an act of power that leads to the intentional bodily injury of others." In this view, corporality distinguishes violence from other means of domination, such as orders, though it contributes to their effect. Since violence injures bodily integrity, it possesses a massive potential for threat and evokes fears. These can contribute to the avoidance of acts of violence, but can also amplify them. The pair of terms 'physical' and 'psychological' violence touch on this connection. Not only does the experience of physical violence, such as torture or rape, have psychological consequences; psychological violence, such as brainwashing, can also have physical effects. Popitz' definition also points to the concept of power. It thus designates the content of violent conflicts as an often unequal structural situation of victims and perpetrators. This underscores that the history of violence is also always a part of societal processes in which the distribution and resources of power are up for discussion.

Beyond its physical core, the term violence has taken on various meanings in the course of the modern age.

1. In the process of state building, legitimate violence is distinguished from illegitimate private violence, independent of whether the latter is wielded in revolutions or in defense of the status quo. The state has defended and extended its monopoly on violence as a constituting component of being a state since early modern times. This monopoly prevailed through the disarmament of the feudal rulers. With the army and (since the eighteenth and especially the nineteenth centuries) the police, state organs exercised the monopoly on legitimate violence. This monopoly required justification in its form and degree, but not in its existence. Lindenberger and Ludtke saw the hallmark of modernity in the network of relationships between physically suffered violence, on the one hand, and the state monopoly on violence, on the other (Lindenberger and

Ludtke, 1995). Thus they not only claim an increase in the state's practice of control and repression, but also touch upon the everyday experience of violence. In the modern age, citizens can come into conflict with state regulations and sanctions which in turn provoke violent actions. In modern protest research, Charles Tilly, among others, has held state reactions to unrest responsible for the extent of existing violence (Tilly, 1975).

2. The experiences of dependency and inequality between the centers of power, colonies, and the so-called 'Third World' led the Norwegian social scientist Johan Galtung to develop the concept of 'structural violence' (Galtung, 1975). From the perspective of peace politics, he drew attention to a discrepancy. He saw a chasm between the existing potential for development based on technology and available societal wealth, on the one hand, and the respective levels of development of disadvantaged groups and countries, on the other. His concept emphasizes not individual perpetrators, but social structures, and not primarily physically experienced violence, but poverty and exploitation. He was not so much concerned with legitimating counterviolence, as vehemently defended by the Algerian sociologist Frantz Fanon, but with social peace, which he thought would be secured for all through equality and opportunities for development (Fanon, 1961). The term 'structural violence' flourished in the 1970s, but also met sharp criticism. It was accused not only of failing to define 'structure,' but also for lacking specificity in its analysis of violence. "By tendentiously deciphering all relations as relations of violence, these relations are leveled," wrote Wolf-Dieter Narr (1973); i.e., the analyses of violence and society are indistinguishable. Galtung was able to demonstrate that the term 'violence' can be applied meaningfully in the analysis of acts in the context of the forcible relations effective in acts of exchange, in inculcating literacy, and in migrations.
3. The concept of symbolic violence is beset with similar problems of distinction. Pierre Bourdieu and Claude Passeron used it in their theoretical analysis of the French school system and thus designated "that form of violence" that "is exercised against a social actor with the complicity of this 'actor'" (Bourdieu and Passeron, 1970). The experience is violent in that the actors are subjected to a code of language and behavior alien to them; it is symbolic through the verbal and semiotic form of its mechanisms. These shape the school's demands and enable or prevent scholastic careers. According to Bourdieu, by accepting this code, the actors contribute to the lasting legitimation of the scholastic system of selection. This term rightly touches on the linguistic and semiotic dimension of violence, but expands it to the point that it no longer has clear contours.
4. In gender history during the 1990s, the concept of violence has been extended to private forms of violence within the family. Feminist literature has used the term 'sexual violence.' This refers to actions that appear in a form tying societies to sexuality. They are carried out against the will of persons who do not have the same power resources as the perpetrators. Sexual violence is thus analyzed as part of the inequality effective in the relationship between the sexes. It shifts from an exceptional phenomenon to one in terms of which the paradigmatically prevailing ideas of power relations and sexuality, and the experiences of women and girls can be grasped. This extension of the concept of violence not only opens new fields to scientific research, but, since the 1980s, has also been taken up in the penal codes of individual societies.

Historical Research on Violence

In the past, experience with violence was subsumed again and again in theoretical sketches. Among them, the theories of Thomas Hobbes, Max Webber, and Hannah Arendt were doubtless the most influential, though they arose under disparate conditions (Hobbes, 1914; Weber, 1919; Arendt, 1970). But, especially since the 1950s, their influence on historical research on violence has been superseded by that of Norbert Elias, Michel Foucault, and most recently Clifford Geertz (Elias, 1976; Foucault, 1975; Geertz, 1973).

Thomas Hobbes was the primary inspirer of historical research on violence (Hobbes, 1914). In seventeenth-century English society, which was no longer integrated by religion, he demonstrated in terms of contract theory the necessity of the state's use of violence. Hobbes postulated that, to pacify an English society composed of private persons hostile to each other, these persons relinquished their rights to the Leviathan state, i.e., in the English case, to the absolute monarch. In return, they received protection from hostile others and the guarantee of societal peace. The double function of the state's monopoly on violence – on the one hand, to protect the interests of individuals, and on the other, to limit their possibilities of self-realization and their rights – has become the common possession of most analyses of violence since Hobbes. The individual's relationship to state violence, thus often develops from his specific experiences either with the state's protection or with its limitation of his freedom. Norbert Elias has provided important stimuli for historical research on violence (Elias, 1976). Elias described European history since the Middle Ages as a history of civilization. This hypothesis is based on two central assumptions. First, Elias says that, in the course of the expansion of the trades, commerce, transportation, and the activity of the state, the interaction among members of society became more frequent and dense. To the degree that they competed for influence and shares of power, agreements on behavior and behavioral norms were required. In this process, civilized manners prevailed. On the other hand, the state monopoly exercised an increased external compulsion over the behavior of the members of a society. This found its most complete form in courtly society. In the realm regulated by courtly etiquette, the individual's success depended on new civilized modes of behavior. To the degree that peoples' definition of themselves conformed to this framework, forms of self-compulsion and control of feelings resulted. Violent structures of interpersonal societal relations receded as the model of civilized and inner-directed acting spread from the upper strata to the rest of society. Elias' historical periodization has been criticized by Hans-Peter Duerr, but his secular-based hypothesis has nonetheless been very fruitful for research (Duerr, 1988–96).

Michel Foucault emphasized the shift in form and content in state practices of punishment, which shaped both societal reality and the individual's life practice (Foucault, 1975). In his view, the practices of domination targeting the body have shifted since 1800 to strategies targeting the mind. The disciplinary measures carried out on the human body in clinics, psychiatric facilities, and prisons took on a more total character in the modern age. As in Jeremy Bentham's 'Panoptikum,' the individual is now subjected to control by institutions and the effects of techniques of power. In Foucault's model, the direct violence of the exercise of power made way for the violence of discourses – at least after the threshold between the epochs, which he locates around 1800. Historical studies have relativized this hypothesis and made it more specific, as they did with Elias' theories, but it too has retained its importance as a challenge to detailed studies.

While Elias and Foucault locate the changing use of bodily violence in epochal contexts and societal macrosituations, cultural anthropological studies have gained importance over the years, and they are no longer devoted to the causes, but to the forms of violence. Attention to the 'how' of the practice of violence, a maximum of 'dense description' of constellations of violence, and even an 'ethics of precision' (von Trotha, 1997) is demanded for the description and explanation of acts of violence and their results. In referring to Clifford Geertz, recourse is taken to anthropological approaches or variants of symbolic interactionism are tested (Geertz, 1973).

Emphases and New Fields in Historical Research on Violence

An International Comparison of Violence

Historical research on violence has so far privileged the national context and has seldom conducted international comparisons. This concentration on the nation-state suggested itself, since the state monopoly on violence stood in the center of research on violence. But there are still some comparative works, based partly on national research or inspired by the latter's questions. Among these is the long-term comparison of the period from the thirteenth to the nineteenth centuries, in which P. Spierenberg describes behavior toward victims, the weak, and animals to demonstrate a general increase of empathy in Europe (Spierenburg, 1991). Charles Tilly formulated a typology of collective violence in Europe, in which he names the parochial conflicts – the feuds between geographical communities (Tilly, 1975). He uses the term 'reactive violence' to designate resistance against state interference in the citizens' way of life. According to Tilly, proactive violence is exercised within those organizations that acquire, and seek to defend, their political power.

All these investigations face the problem of having to work with unequal and incomplete national data. Since forms of protest and criminality take different cultural shapes in different societies, views of reality are often grasped as reality itself. In comparative research on revolution, violence has often not been accorded central importance. The only exception is Arno Mayer's study that contrasts the violence of the French and the Russian Revolutions (Mayer, 2000). Finally, research on totalitarianism has pinpointed state terror as a central instrument of totalitarian systems. Dietrich Beyrau has presented a critical, detailed analysis contrasting and comparing violent state measures (Beyrau, 2000). It elaborates the similarities as well as the differences between the violence of the National Socialist and that of the Stalinist systems of rule. These comparisons had been continued by Michael Geyer and Timothy Snyder. Comparative studies permit discussion of the charged question of modern research on violence: whether private and public violence dwindles in or is compatible with the functioning of modern society.

Collective Violence as Social Protest

Research on protest is one of the most flourishing branches of research on violence. The extent and significance of acts of violence are examined in it. It has taken on new contours since the 1950s, under the influence of English, often Marxist-inspired social history and of the 1960s American research on urban riots. Insight into the inherent logic of popular action has supplanted the condemnation of rage-blinded, aggressive mob, and crowd activity. Their violent nature has been interpreted less as a defining characteristic than as an aspect of social protests and less as irrational than as a rational strategy. Georges Rude and Edward P. Thompson in particular have carried out this revision (Rude, 1964; Thompson, 1971). Thompson has also drawn attention to the 'moral economy.' With this term, he designates the model of violence as a fitting behavior by peasants, artisans, and workers in response to the markets in times of economic crisis or famine. Acts of popular violence in Great Britain during the transition from the eighteenth to the nineteenth centuries are set in relation to this model and contrasted as a traditional alternative to the developing market society. Thompson's continuing hypotheses that these protests were directed against the gentry have meanwhile been revised. Nevertheless, building on Thompson, attention has shifted to the significance of violent protests in a strategy based primarily on negotiating and compromising with the authorities. In this context, John Bohstedt speaks of a 'protocol of riot' that the protesters strictly adhered to, in order to initiate negotiations, rather than destructive activities (Bohstedt, 1988). When violence was nonetheless employed, its form was often borrowed from traditional rituals or it was applied symbolically against objects. Between 1770 and 1850 in Great Britain, France, and Germany, the majority of protests against hunger, tax revolts, and resistance against conscription were usually conducted nonviolently. Following the American urban unrest, Graham and Gurr later questioned this hypothesis of violence's positive significance for negotiating processes (Graham and Gurr, 1969). They underscored that violence is, as a rule, unproductive, while in Charles Tilly's interpretation of violent means as part of power struggles, they can indeed be successfully employed (Tilly, 1975). New research is now asking whether traditional scripts of food riots are taken up by protest against high prices and food shortage during and after the two world wars.

Since the mid-1980s, this still influential view of protest has been accused of attributing too much rationality to it and of denuding it of its emotionality. Alain Corbin in particular has pointed out the degree to which fears, hopes, and rumors have been responsible for acts of violence (Corbin, 1990). George

Lefebvre already traced plundering and acts of violence against the landed nobility in France in 1789 to the effects of alarming news and fears in the rural population (Lefebvre, 1970). For his part, Corbin describes how, on a market day in August 1870, a crowd of 300–800 people tormented a young noble and then burned him alive. He had been accused of being a Prussian and of calling out 'Vive la Republique.' These acts, like the Grande Peur in the French Revolution, can be traced to the spread of rumors, but that does not explain their cruelty. For historical research on protest, this finding suggests that violent activity should be understood as part of a history of the emotions. A growing actual interest of historians in emotions, their origin and effect in different surroundings, will surely develop this field (Bourke).

The investigation of the history of violence has not been limited to the extent and significance of acts of violence but has also asked about its instigators and causes. The mass psychologist Gustav Le Bon has attributed mass violence primarily to women (Le Bon, 1908). Historical research on protest has shown that women have indeed taken part in acts of violence. But women remained in the minority and were more intensely active when the well-being of the family was at stake for instance in food riots than, for example, in conflicts with the military. But they were also victims of police repression when they attacked the property or public rules. In order to determine the actors of violence, the social profile of people arrested for manifestations of violence has been worked out. They usually do not come from the 'Lumpenproletariat,' but are rural and urban wage earners, sometimes from tradesmen milieus. The people, more than the mob, carried out these actions. Bohstedt, in particular, has pointed to disturbed societal relations as one of the causes of violence in Britain, especially where social contact and dependencies between the upper classes and the masses were attenuated (Bohstedt, 1988). In his study of extreme international violence, Christian Gerlach is also stressing the importance of crisis. But it remains open whether this hypothesis can be confirmed for other protests. Whether acts of violence always followed social disintegration, and whether rituals of violence do not in turn presuppose relatively unified communities is a question for additional research. In the past, historical research on protest has concerned itself most with the phase in which civic society was formed. But now it is also examining the period between the world wars as well as the second half of the twentieth century and is including the problem of political violence to a greater degree. Its approaches and methods must now prove themselves in this field.

Historical Research on Violence as Crime

Violent crime in its long-term historical development, societal distribution, and meaning has been investigated primarily in terms of Europe in the Middle Ages and early Modern Age, and in terms of the twentieth-century US. Modern historical studies of crime that also address nineteenth- and twentieth-century Europe are rare. Quantitative international comparative studies of violent crime often exhibit methodological deficiencies, because the database in the individual countries and through time is uneven, and above all because the prevalence of recorded acts of violence determined also depends on the strength and severity of prosecuting authorities. Additionally, Eastern and Central Europe have been almost completely omitted from almost all long-term studies due to the lack of research there or to language barriers. Nevertheless, trend analyses from a bird's-eye perspective can provide hypotheses that can then be worked out in detail or modified by historical microstudies. Spierenberg hypothesized a drop in the rate of homicide in Europe before 1850 (Spierenburg, 1991); in contrast, studies of Western Europe and the US from 1800 to the beginning of the twentieth century by Gurr and Lane find a rising rate of crime and homicide in the US (Gurr et al., 1977; Lane, 1997). These rates allegedly fell in the century from 1840 to 1940, only to rise again in the middle or end of the 1950s, but individual studies of crime in discrete nation-states or cities do not confirm this chronology. American research has confirmed the hypothesis that the US was, and remains, the most violent nation among the Western democracies. But it is still debated whether this can be traced primarily to 'frontier violence' (Hollon, 1974) and its consequences. In Europe, during the last 50 years homicide rates are rising again as a consequence – as Manuel Eisner is suggesting – of economic polarization and cultural individualism.

Modern research on crime focuses on the relationship between delinquents, the penal system, and prosecution. Social history concerns itself with the social origin and situation of criminals; legal history and sociology investigate penal 'labeling,' which criminalizes specific behaviors; and institutional and political history is devoted to the construction of prosecuting bodies. Nicole Castan and Gerd Schwerhoff, among others, have conducted historical studies of cities or regions, examining premodern societies. The following general finding resulted. Until the early modern age, even homicide was an infraction that was not punished automatically by death, but it could be atoned for and expiated through rituals and payments of money. In sixteenth-century Germany, laws called for more severe punishments, but court practice was orientated more toward requiring expiatory measures benefiting the surviving relatives than toward retaliation. This assessment of violence was not surprising in a time that still accepted it as a definite part of societal practices and rituals in the premodern period. Among youth, villagers, and journeymen and masters in trades, not only were conflicts resolved by violence, but initiation rites were also organized around violence. The criminalization and limitation of violence is a process that began in the early modern age but did not fully prevail until the full-blown modern age. For France, and based on the discourse of elites, Muchembled reports on rapid advance of the process of civilization, locating the criminalization of homicide in the eighteenth century (Muchembled, 1988). But even for the eighteenth century, doubts have been raised whether the draconian penalties prescribed can be regarded as an indicator that more severe norms prevailed, or if these penalties were intended to compensate for the weakness of prosecuting authorities.

For it has been pointed out that, precisely in premodern times, legal jurisdiction and police control had not thoroughly penetrated into rural communities in a number of European societies. For the nineteenth century, Peter Gay has advocated the hypothesis that, despite the criminalization of violence, it was indeed tolerated in specific societal areas, to the degree that it remained limited to and ritualized in them (Gay, 1993). He

adduces the examples of the duel and students' fencing to gain scars, corporal punishment in schools and the army, and violence within marriage. The question of when which practices were prosecuted judicially and considered illegitimate violence has not yet been investigated adequately in international comparison.

Recent Approaches of Historical Research on Violence

Historical research on violence has taken on new dimensions in the newer style of the history of war and the military. The latter is concerned with military perpetrators of violence that exceeds normal military action: participation in mass executions, acts of annihilation, torture, or rape. Browning and Bartov have been exemplary in pursuing this approach in studying National Socialist police troops and the *Wehrmacht* on the Eastern front, respectively (Browning, 1992; Bartov, 1985). Concentrating on military perpetrators opens up the analysis of wars that accompany decolonization, the Vietnam War, and warlike conflicts accompanying the collapse of the bipolar world order. Beyond the discovery of formerly unknown or repressed atrocities committed by soldiers and officers, attention has focused on analyzing the causes of such inhumane behavior. Current discussion addresses the question of whether specific images of community and or group cohesion motivate the perpetrators. Beyond soldiers' and officers' motivation, interaction, and acts, research is also concerned with how they deal with experiences with violence. To the degree that interest in the history of memory and experience increased, the effects of violence on postwar societies has also been researched. World War I has been more thoroughly considered than World War II. Even today, it is becoming clear that societal discourse on wars and on the legitimacy of the violence exercised in them has as large a role as direct experience of violence in dealing with the past. It turns out that there is a need to correct the one-dimensional assumptions that experiences on the front are transformed directly into a brutalization of postwar behavior.

The construction of the state monopoly of legitime physical violence – as Max Weber defined it – has been part of studies on state building. But this interest has overstressed the implementation of this monopoly which was equal in time and space. State monopoly for instance was more hegemonic in France than in Italy, where the Mafia organizations used frequently violent means to defend their interests. In several countries, zones of limited statehood continue to exist in which warlords used military violence in order to assure their dominance. This approach has been used in order to explain the barbarous violence in African societies during the last 5 years as well as the atrocities of civil wars. But nation-states themselves are actors of uncivilized and uncontrolled violence either in the context of colonization and decolonization. Or by acts of 'ethnic cleansing', which is considered by Marc Mazower to be more widespread than genocides during the twentieth century. This approach is situating – as the recent studies on genocide are doing – violence in a broader historical context.

Historical studies on terrorism were more frequent after 9/11 than before, but even then the scientific outcome is rather limited. The wave of anarchist violence at the end of the nineteenth century and its ideological protagonists (Kropotkin, Bakunin, etc.) attracted a lot of attention as well as the terrorist organizations, their actors, and the state reaction to them in Western Germany, Italy, and France. Those studies are focusing often on national cases and comparative views are the exception. Terrorism is often situated in the relationship of state and terrorist groups and explained by an aggression–reaction schema. It was also perceived as a communicative act by which terrorist groups tried to provoke state power by their demands. Those studies which shared this interpretation insist on the media coverage and stress performative acts.

Research on violence has profited in the late twentieth century from interest in questions of cultural history. In this context, the taboo against violence is no longer seen as the dominant characteristic of the modern age, whose ambivalence Baumann has underscored (Baumann, 1991). The media's conveying and staging, which depicts and overemphasizes acts of violence, have contributed to this ambivalence of the modern age. These connections are often mentioned in current diagnoses, but there is a lack of comparative historical research devoted to the respective cultures of violence in various milieus and at various times. For most epochs, not even the discursive boundaries between violence and nonviolence are well enough known. Special attention should be paid to the degree to which state authorities and the upper strata of societies have intervened in the justification of forms of violence and in its condemnation (Haupt). For the respective concepts of violence, all have a mediating link between the state monopoly on violence and everyday experience.

Violence in Anthropology

Kay B Warren, Anthropology Department, Brown University, Providence, RI, USA

Abstract

Anthropologists have moved away from static categories and hierarchies of violence, commonly used by other disciplines, and toward the dynamics of continually interacting and transforming formations of violence. This article illustrates contrasting dynamics of violence for the Cold War and post-Cold War periods. It shows how anthropological perspectives complicate assumptions made about transitions from 'war' to 'peace.' Anthropologists offer new perspectives on war and peace, truth and reconciliation commissions, illicit migration and human trafficking, health care for impoverished urban sectors, and humanitarianism in action.

Introduction

The study of violence in the field of anthropology has been reshaped in response to a sea change of global transformations and regional conflicts. Anthropologists have moved away from the study of discrete categories and hierarchies of violence, commonly used in other disciplines, toward the dynamics of continually interacting and transforming formations of violence as they are mediated by institutions and ongoing social relations. In the process, anthropologists no longer see 'warfare' and 'peace' as discrete stages or states of being. The 'violence paradigm' – that distinguishes predator, victim, and audience – is no longer convincing.

The roles of civilians in warfare and the impact of war on civilian life immediately complicate these relations. In Latin America's counterinsurgency wars of the 1980s – when state armies fought revolutionary forces – armies on both sides were composed of civilians with limited training and unsophisticated arms. State authorities forcefully recruited boys and young men from schools, family farms, and their workplaces. Rebels found foot soldiers among leftist volunteers. They were joined by families that fled their communities when army patrols used scorched earth tactics in the countryside. After seeing dead bodies along the road, young community leaders in schools, religious groups, and local committees grew anxious that their names might appear on the local assassination list. Should they stay and keep a low profile where they were or leave and join the other side which, in fact, was not strong enough to guarantee their safety?

Anthropologists illustrate how war lives on through its after-effects and the violent fragmentation of people's lives. In Guatemala City, the gangs that poor joined as youth groups and alternative families in the mid-1980s became increasingly brutal in the 1990s as they affiliated with organized crime. The extreme violence they came to practice had its roots in the hardest moments of the counterinsurgency war.

Dispossession occurred after these wars as well. State-mandated relocation programs sent families away from 'dangerous' borders, leaving them without basic resources. Agriculturalists lost their lands and social networks in the process. Some turned to the anonymity of city life. Others joined the surge of internal refugees. Many fled for their lives to other countries, such as Mexico and the United States. There is no universal story of the struggle to survive these wars. It is clear that the erasure of civilians from scholarly accounts of war needs to be rectified.

Cold War Agendas for Anthropology

Across the Cold War and the collapse and transformation of state socialism (1946–89), research on violence followed great power tensions, clashing ideologies, and violent authoritarian states. Land, labor, class conflict, state's regulation of national markets, and other aspects of single-party governance were key aspects of socialism in practice. Analysts have documented socialist regimes and counterinsurgency armies in many parts of the world. Other formations of violence – including ethnic nationalism, sectarianism, racism, communal violence, genocide, and organized crime – complicated and/or served the interests of these political systems in different parts of the world.

During the Cold War, social scientists on the left in the United States, Europe, and major zones of conflict circulated important critiques of capitalist imperialism and colonialism. They demonstrated how the dynamics of structural violence in these economies reproduced inequality for urban workers and rural peasants. Precarious families faced physical violence, small unstable incomes, life-threatening poverty and debt, disease, and high rates of child mortality. Activist researchers supported anti-imperialist agendas and participated in solidarity movements, speaking out at major forums. Engaged scholars collaborated with their regional counterparts, especially in Latin America, on agrarian histories, studies of repressive regimes, and indigenous issues. The 400-year history of elite racism as a form of coordinated governance through the church, military, and government was another line of path-breaking work. Others were involved in long-term innovative community and regional studies. Histories of rebellions, revolutions, urban violence, and activism that challenged the status quo have been important products of this research.

These scholars and public intellectuals generated critiques of violence and capitalist governance for international audiences. Many stressed the regional dynamism of struggles and agendas for change. The special brutality of counterinsurgency warfare was revealed in the dual goals of crushing revolutionary

movements and preemptively punishing civilians who might at any point become politicized and join rebel forces or oppositional organizations. Counterinsurgency wars in Latin America involved genocidal violence, mass killings, widespread 'disappearances,' and decentralized military bases that detained and tortured suspects who came to their attention in the routine surveillance of nearby towns and cities. Spies were everywhere; public buses were routinely stopped and searched for subversives by armed soldiers. No matter what the age of the bus rider, a regional knit bag from an activist area or a small tape recorder was seen as a signal that someone was politically dangerous and likely to be involved with the rebels.

National organizations on the popular left challenged state violence with independent research and public protest. Activist groups came together in public to personally testify about the human cost of state violence, holding up jarring photos of the 'disappeared' in their families. Critiques of human rights abuse, labor exploitation, and state violence were discussed and circulated by activist research groups and featured at major events. In some instances, this was a hotly contested process. Human rights, particularly labor rights, were denounced by conservative critics as dangerous revolutionary claims rather than as internationally accepted liberal norms. Peace activists were denounced as communists.

In spite of continuing repression, research was done in support of the peace process. The international community supported respected researchers who produced accountings of civilian and armed forces deaths on both sides for official truth and reconciliation committees. Locally, townspeople were able to pursue something that had been too dangerous to undertake during the war. They disinterred corpses of loved ones from secret cemeteries hastily created by the troops after massacres in order to do their own personal accounting and mourning of the dead. Years after the massacres, these were still risky ventures; in some areas local activists were aided by professional forensic anthropologists who used their scientific training to identify remains and establish how individuals died.

This historical period produced new kinds of political media. To draw international attention to and humanize shocking mass violence in faraway places, which had received limited international media coverage during counterinsurgency wars, the Cuban government gave awards for outstanding books based on the testimonies of indigenous Marxists, mine workers, and women activists for their struggles against capitalist exploitation and repression in Latin America. Feminist anthropologists in the 1980s documented labor abuse and exploitation in newly emerging workplaces, most especially at maquiladoras – huge 'offshore' factories in special economic zones with high-volume assembly lines operating under the deafening din of modern machinery. These young Third World women were under constant pressure to keep up with work quotas that wore out their bodies as they assembled clothing for mass markets in the United States.

Postsocialist Transition versus Armed Forces Demobilization

Research agendas changed dramatically after the end of the Cold War. State-managed socialist economies in China, Vietnam, Russia, Eastern Europe, and socialist countries in Latin America and Africa took different paths in their transitions to market economies. Research turned to economic globalization, neoliberalism, the privatization of government functions, and new forms of warfare. The opening of Cold War borders took center stage as did transnational research on governance and conflict within and across world regions.

Post-Cold War formations of violence took new turns as rebels lost momentum and the UN oversaw negotiations between key parties in a peace process that sometimes took years to negotiate. Reforms called for cuts in the size of the army and the demobilization and disarmament of rebels. Well-known rebels and leftist activists turned to party politics and the electoral system. As former soldiers looked for employment, gangs formed that engaged in extortion, murder for hire, robberies, and illicit commerce. Crime rates increased. The principals of progressive rural schools supported by international nonprofit organizations were objects of extortions and shake downs, streets continued to be unsafe at night, and daylight robberies were common. Violence reflected the corruption of authorities, the failure of the criminal justice system, the power of organized crime, and transnational scope of neoliberal markets. Lynchings, that is, spontaneous collective violence against individuals judged by the local community to be criminals, was practiced in the cities and countryside. Some attacks on foreign women tourists were the result of fast-moving local gossip that the tourist's real motive for visiting the countryside was to steal babies or children and take them home to the United States. This is part of a wider anxiety about the adoption market, brokered by elites, between countries like Guatemala and the United States.

Anthropologists and related scholars have written powerful post-Cold War works on globalization, neoliberalism, political violence, security, counterinsurgency warfare transitions, and transnationalism. They have researched different world regions and traced the dramatic growth of informal economies, organized crime, and large-scale illicit businesses, networks that serve as forms of governance in weak states in Africa and Latin America. One can hear the echoes of these abstract issues in the day-to-day life and violence of urban neighborhoods and local communities.

The Anthropology of Care, Public Health, and Humanitarianism in Neoliberal Times

The scope of the anthropological project has grown as researchers questioned the conventional emphasis on violence as the state's monopoly over the use of legitimate force by the armed forces, police, and judicial systems. Cultural anthropologists have chosen not to uniquely privilege formal institutions or physical harm in their studies. Rather they include informally instituted structures of violence generated in situations of civil war, state terrorism, fragmented states, globalized economies, and the marginalization and dispossession of individuals and communities.

In the process, the 'anthropology of care' has taken on seemingly intractable social problems and shed new light on the paradoxes and possibilities of current systems and practices of care for people at the margins. These ethnographic case

studies interrogate neoliberal market expansion into impoverished urban neighborhoods, as well as the extension of state services dealing with addiction into areas outside larger cities. At issue is whether new models of health delivery can gain effective access to the poor and their needs, and what happens when larger systems fail to effectively connect. How do people at the extreme margins take care of others when the wider system fails them?

Anthropologists pursue the many faces and paradoxes of humanitarianism and the relation of humanitarianism to governance. The transnational recruitment of cheap labor, the targeted closing of borders to dangerous or undeserving others, and deportation regimes are some of the compelling issues in this line of research. Making ones' way across borders is a powerful challenge. The technologies of border surveillance pursue access to everyday social life, individuals' backgrounds, and personal intentions (Miriam Ticktin, 2011). Interviews by state authorities generate unbearable anxieties. The interviewer demands answers to key questions. To be convincing, answers need to fall in the domain of the right answers and convey the correct effect. In practice, however, ideal answers continually change as do the officials. Those trying to gain special visas for access to health care on humanitarian grounds face these dilemmas. They had to impress officials in these interrogations to stand a chance for a visa. These processes echo some aspects of the arbitrariness, unfairness, and inefficiencies that Akhil Gupta (2012) addresses in his discussions of bureaucracy, structural violence, and urban poverty in India.

2. Truth and reconciliation processes
3. A crime with many names: human trafficking, modern day slavery, and the transportation of undocumented migrants by organized crime
4. The anthropology of care, public health, borders, and humanitarianism.

Transitions: War and the Ironies of Peace

Diane Nelson generates innovative framings and analytical momentum from post-structuralist and feminist theory in her book "*Reckoning: The Ends of War in Guatemala*" (2013). This work exposes problematic forms of structuralism in social scientific and cultural research framings and media analysis. Her analysis stresses transitions in a very different and more critical analysis than the mainstream's focus on peace, democracy, and business expansion. She responds to current discussions of the shift of socialist to postsocialist governance with new directions for research on transitions. Nelson critically engages the political and moral dilemmas that accompanied the 'capitalist victories' of the 'peace process' with its focus on 'democratic' and 'market-oriented governance.' She argues that 'reckoning' is a very revealing political process that benefits from her critical positioning with its unconventional and innovative mix of critical theory and ethnographic engagement. Her most striking move is to posit virtually universal participation and complicity in the morphing patterns of violence across transitions. Grassroots Marxist rebels leave their weapons and Cold War grammars of conflict to be absorbed by the market economy, illicit economies, and maquiladora production for international markets. The greater contact between Mayans and the United States than ever before starts with rural refugees fleeing genocidal violence who become transnational labor migrants, providing new sources of income for their families, and gaining membership in violent gangs anchored in LA and Guatemala.

A hidden wound appears in her work, one that addresses an unspeakable question for anthropologists and activists during the counterinsurgency war: 'Was the insurgency a mistake or not?' The question is whispered by Nelson and others in fleeting terms.

Her coedited book with 'Carlota McAllister *War by Other Means: Aftermath in Post-Genocide Guatemala*' (2013) is a very successful collaborative engagement with the continuing after effects of 'la violencia,' as it is called in Guatemala. The article in this book explore new formations of local and transnational violence. They pursue the internalization of violence in rural and urban populations, especially in gangs, lynchings, and attacks on foreigners.

Truth and Reconciliation Processes

Anthropologist Kimberly Theidon (2013) has contributed to innovative critical studies on truth and reconciliation commission (TRC) processes. Her perspective cites the power of postwar human rights activism to create technologies that establish the truth of particular genocidal events in order to create paths for reconciliation through TRC processes in different parts of the world. In tension with this view, she pursues the project of documenting community responses to situations of extreme violence in the 1980s, especially the legacies of rebels seeking to overthrow government and counterinsurgency soldiers responding with widespread violence designed to halt radicalization.

This work transcends fragmented accounts that TRC interviewers classically produce with their templates of issues and lists of questions. By contrast, Theidon pursues carefully contextualized ethnographic work on the interpersonal contours of violence, how local communities dealt with and continue to deal with fellow residents who were Maoist Shining Path sympathizers and rebels during and after the war. Theidon offers a gender-inflected account of the impact of peasant soldiers who occupy rural communities and their sexual violence against women. Anti-Shining Path community organizing was also violent, another legacy for widows, single mothers, and their children.

This ethnographic approach generates original findings on masculinity, class, and violence; on women's battles to limit antagonists' violence against their children, at a substantial personal cost. Theidon's ethnography highlights the contrast between the goals of the TRC processes, which offers the psychological therapeutic recovery of memories of violence versus the local Quechua community attempts to live together with their own construction of reconciliation, 'by letting go of hateful memories.' Theidon's commitment to the legitimacy of indigenous representations of reconciliation versus her own preference for the establishment of TRC reparations for women

who were raped during the conflict and militarization of these communities is fascinating.

Illegal Migration: A Crime of Many Names and Competing Forms of Governance

There have been a variety of constructions of illegal migration: 'human trafficking,' 'modern day slavery,' and the 'transportation of illegal migrants across borders.' Anthropology and related fields have examined the implications of these rhetorics for criminalizing migration and concentrating on deportation as a dominant form of state governance (De Genova and Peutz, 2010; Hansen and Stepputat, 2005; Ticktin, 2011; Warren, 2012).

Activists, governments, and scholars use the term 'human trafficking' to identify labor recruiters and criminal organizations that treat job seekers as commodities that can be bought and sold. Criminal organizations look for migrants who can be convinced to take what are often demeaning jobs at a great distance from their homes and social networks. While these jobs may be idealized by recruiters/traffickers, they are often similar to jobs at home but with the promise of better pay. Human trafficking is often assumed to be sex trafficking, that is prostitution. But many other kinds of work are offered to people seeking employment: jobs that involve physical coercion, exploitation, and irregular pay. For instance, labor migrants to the United States from Central America are recruited to harvest fruits, vegetables, and tobacco; work in slaughterhouses; take on graveyard shifts cleaning buildings or restocking shelves; and as live-in domestics. The legal issue that determines if people are victims of the crime of human trafficking is whether individuals have given 'their consent' to work in these jobs or whether they are forcefully coerced by recruiters and kept by supervisors in situations without being paid or are faced with violent threats if they do not meet production quotas. These jobs commonly require labor that is physically dangerous and subject workers to demeaning treatment as objects in labor markets. In some cases, people are in effect bought and sold as they are parceled out to work sites. They are controlled by inflated debts they must repay to cover recruitment fees, transportation to jobs sites, and forged travel documents to cross-national borders. Additional fabricated expenses such as paying off fines for breaking 'rules' invented by their handlers are common practices. Extra fees for housing, food, clothing, and medical care are deducted from workers' pay, with or without a formal accounting. Workers generally pay off these illegal debts to regain freedom of movement, just as they would in their home countries if they worked on Central American plantations or urban businesses. These forms of regulation are exploitative and abusive; they violate recognized but often unenforced human rights. An alternative term for these situations is 'modern day slavery' (Bales, 2008). This term includes many different kinds of work that force people into slave-like conditions in different parts of the world. For instance, these practices include the exploitation of youths who are controlled through debts inherited across generations, which means they are bound to menial work to pay debts that they may not fully understand. Youths work very long shifts and often receive token compensation, beyond food and improvised housing, for jobs in brick making, agriculture, and domestic service. Or they may be forcefully recruited into armies – national and rebel forces – in conflict zones. They become indentured workers who cannot leave their positions. International law criminalizes the recruitment of youths and children under 18 years of age for these and other kinds of work because they are too young to give their own legal consent to work. A third approach focuses on the illegal transportation across borders by organized crime and the work of border governance to criminalize and stigmatize migration and organize deportations. These forms of state regulation often stand in tension with the government's active promotion of migration for its citizens. In Latin America, for example, governments with international development assistance from the United States and the UN have developed nonformal education initiatives to educate citizens in safer work choices for migrants (Warren, 2012). In many countries, much of the national population sees their future in terms of tactical migration. There are too few job opportunities, little continuing education, and chronic violence for the urban poor at home. Many families dream of escaping to better job markets or to joining members of their families already working in the United States. There are ironic forms of governance at play in this situation. Each construction of migration, as 'human trafficking,' 'modern day slavery,' or 'competing forms of governance' has its own complexity. Undoubtedly more emphasis should be put on the role of organized crime in migration.

The 2014 crisis of unaccompanied youths and children crossing illegally into the United States and surrendering to border authorities is the result of an aggressive and cynical scam. Criminal organizations – in a move to diversify their operations beyond serving as brokers for the drug trade which caters to the lucrative demand from the US and European consumers – are selling Central American families made-up stories of easy visas and successful family reunification if they have a parent or other relatives living in the United States. They have extorted thousands of dollars from each impoverished extended family to take their youths and children to the Promised Land. These recruiters failed to disclose the truth that this wave of migrants will most likely not be allowed to stay in the United States without visas. These youths and children risked death and sexual violence along the way. In seeking a better future for their children and an escape from chronic urban violence, corruption, and unemployment in their home communities, their families have assumed extraordinary debts. However lucrative the scam has been for organized crime, it has been a very cruel one for everyone else.

The Anthropology of Care, Public Health, Borders, and Humanitarianism

Cultural and medical anthropologists have chosen to study the daily practice of formal institutions and their capacity for physical harm rather than healing through acts of omission. They also seek to understand the social fragmentation and suffering generated by informally instituted structures of violence (Das, 2007). Governments often picture inner cities as zones of lawlessness; in contrast, researchers discover that marginal neighborhoods are products of urban policies that condemn these neighborhoods as hopeless and dangerous. There are few legal job opportunities for adults and young

people in underclass urban zones. Governments provide few public services, given prioritized decisions that limit funding. As a result the schools are inadequate. Marginalized urban life in much of Latin America is dominated by gang violence, corrupt policing, organized crime, and lucrative illicit economies. It is a nexus of both precarity and care.

The 'anthropology of care' has become a major site of social critique. Anthropologists have successfully used ethnographic methods to pursue case studies of chronic poverty in the United States and other world regions. They are studying drug addition, inadequate health services, criminal gangs, and state violence, particularly but not uniquely in urban settings, as understood in their wider regional and institutional contexts.

With neoliberal economic reforms, more of the burden of care falls to families and kinship networks in the United States. Angela Garcia (2010) worked on state programs in New Mexico that deal with chronic drug addiction and found many barriers to successful treatment built into these programs. The larger program, funded by the state, was broken. Garcia found patterns of love and care between mothers and daughters at home to calm the suffering of withdrawal. In effect, securing drugs for their adult children when the clinic refused to help them has become part of the cycle of care. She wants readers to understand the dynamics of this situation, tied to the state funding and addiction treatment norms and to the corrosive poverty of these communities with few options for work. The reality is that there is no place in these settings to be outside heroin; the drugs are everywhere. In a fascinating argument, she ties this existential dilemma to the longer history of these communities' dispossession from the lands that their families had worked and owned in the historical past.

Clara Han, in long-term research in Chile, learned how the urban poor had to cope with a very violent and fragmented environment – drugs, gangs, violent policing, and economic pressures that require the continual balancing of social obligations with limited financial reserves since so little stable work was available. In order be involved in the care of others, these urbanites have found ways to create their own social networks and forms of care by making use of shared credit cards, something they are able to do as the financial industry has recently looked for ways to expand their client base for credit cards and debt (Han, 2012).

It is in these dilemmas that anthropologists come to understand the deep desire to help others and the limits that corrosive poverty and violence places on the possible. There is inevitably a larger range of constraints – which these researchers identify for each particular situation – that limit people's options and shape their moral dilemmas. The challenge for anthropologists and others is to see the humanity in these situations.

Public health on a much larger scale is another arena for critical anthropology. At issue is the potential and limits of market economies in progressive governments to create new systems of public health delivery. In Brazil, the economics and politics of public health have been the center of a series of innovative policies dealing with international markets, which has widened the access of the poor to public health resources in crises such as HIV/AIDS treatment and allows people to live full lives with HIV/AIDS as a chronic illness. João Biehl (2007) produced a path-breaking multisited study of Brazilian governance and public heath bureaucracies in action. Biehl produced a wide-angle view of the multinational production of drugs in India and Brazil's negotiations with international drug companies to lower the cost of medications, to create the possibility of state health-care delivery that could widely radically increase the poor's access to drugs for HIV/AIDS.

João Biehl and Adriana Petryna have joined with other investigators to produce an international volume of case studies dealing with critical public health studies (2013). These studies examine the biopolitics of health and disease and the neoliberal state's role in regulating bodies and human life in the context of the circulation of new health technologies and the operation of treatment regimes in very different local social and political contexts with striking inequalities of access.

Abstract

Public violence is episodic social interaction that immediately inflicts physical damage on persons and/or objects, results at least in part from coordination among persons who perform the damaging acts, and occurs at least partly in publicly accessible spaces. Forms of public violence differ with respect to (1) extent of coordination and (2) salience of damage in the social interaction. Cross-classification of (1) and (2) yields five rough types: organizational outcomes, coordinated destruction, opportunism, fragmented resistance, and violent games. All five types of public violence depend heavily on adjacent nonviolent political processes.

Visibly violent social processes simultaneously attract and repel analysts of human behavior. War, rape, genocide, assassination, assault, football, looting, official execution, collective suicide, mutual flagellation, automobile collisions, airline crashes, gang fights, and struggles pitting police against demonstrators all qualify by some definitions as public violence. Most of them regularly attract headlines when they occur – the more extensive, public and grisly their consequences the bigger the headlines. Violence makes the news.

In these circumstances, reporters and readers commonly turn to very simple explanations: some humans are violent in nature, others peaceable, so violent events occur when violent people congregate and enjoy free rein. Unfortunately for that sort of explanation, the boundary between violent and peaceable people actually blurs badly. Even individuals who participate energetically in violent events generally spend most of their time and energy on nonviolent activities. Meanwhile persons who live mostly peaceful lives occasionally get involved in organizing or perpetrating violent activities, for example, by doing military service, serving on juries, or engaging in contact sports. Other people who flee violent interactions in their daily routines nevertheless support one variety of public violence or another in the proper circumstances, for example, by voting for candidates who favor the death penalty, by cheering one group of nationalists in their competition with rivals or by cooperating in what they call a just war. Indeed, most citizens of most states distinguish sharply between coercive acts committed lawfully by duly constituted agents of their own states (legitimate force) and similar acts committed by other people (illegitimate violence). Nonviolence is a beguiling principle, but one honored more in the breach than in the observance.

In general discussions of the subject, three competing views of violence prevail: as propensity-driven behavior, as instrumental interaction, and as cultural form. Treatments of violence as propensity-driven behavior locate its causes within the actor, calling attention to genetic, emotional, or cognitive peculiarities that incline a given individual, group, or category of persons, to damaging behavior more than others. Portrayals of violence as instrumental interaction characterize everything from petty assaults to all-out warfare as means (however inefficient and self-defeating) to power, wealth, prestige, or other ends. To call violence a cultural form – as in the claim that because of the frontier, slavery, or capitalist competition the USA has an exceptionally violent culture – argues that the ready availability of certain ideas, practices, models, and beliefs itself promotes violent action.

The three views suggest very different approaches to inhibiting or promoting violence. Propensity-driven violence calls for the alteration or inhibition of motives, instrumental violence for shifts of incentives and outcomes, cultural violence for teaching new ideas, practices, models, and beliefs. Alas, none of these three broad approaches to violence has yet yielded systematic explanations of the genesis, trajectory, outcome, or sheer variety of public violence as a whole. Perhaps we await the social scientific Isaac Newton who will detect underlying regularities in all the diverse phenomena people call violent. More likely the notion of violence resembles such other widespread but diffuse terms as disorder and goodness: morally powerful categories that do not refer to any causally coherent domain.

In any case, the word 'violence' almost always arrives with baggage of disapproval. The distinction of violent from nonviolent social interactions usually depends on a moral boundary, or at least activates one. Precisely because of that moral charge, advocates of one cause or another frequently extend the term 'violence' to varieties of harm far outside the range of direct, short-term infliction of physical damage on one person by another. They label hate speech, pornography, poverty, unemployment, malnutrition, and other ills as forms of violence. To call a phenomenon virtual violence is to condemn it, to claim that it damages something valuable even if it produces no physical destruction in the short run. As a consequence, every social scientific attempt to delimit, describe, classify, and explain public violence generates controversy. This attempt will be no exception.

We can nevertheless discipline the inquiry by adopting a restrictive definition of the phenomenon under analysis. Public violence, for present purposes, refers to episodic social interaction that:

- immediately inflicts physical damage on persons and/or objects

[†] In memoriam: Charles 'Chuck' Tilly (1929–2008)

- results at least in part from coordination among persons who perform the damaging acts
- occurs at least partly in publicly accessible spaces.

(The ensuing discussion will, however, extend 'physical damage' to forcible seizure of persons or objects over restraint or resistance.) At one edge, such a definition excludes strictly individual, private, impulsive, and/or accidental damage to persons or objects. At the other, it excludes long-term, incremental damage such as communication of infectious disease, cumulative wear and tear, exposure to toxic substances, and death hastened by neglect or social pressure. Nevertheless, it includes an immense range of social interactions, from minor scuffles among rival groups of voters to wholesale civil war. Despite a century or more of effort, social scientists have not so far assembled any reliable, important and systematic body of knowledge that applies to the whole range thus defined.

We therefore have no choice but to differentiate, reviewing analyses of narrower phenomena that bear some family resemblance to each other, probably share some causal processes, and have attracted sustained scholarly attention. Assuming episodic interaction in publicly accessible space, at least a little communication among actors, and some minimum of physical damage to persons or objects, Figure 1 combines the extent of coordination among damage-doers and the salience of damage in the overall pattern of interaction to produce a crude typology of public violence. ('Low' coordination means individualized action with little collective planning and signaling, while 'High' coordination means activation of differentiated and bounded organizational structure with extensive planning and signaling. 'Low' salience of violence means that most of the social interaction involved produces no short-term physical damage, while 'High' salience means interaction strongly concentrated on damage.)

Other distinctions come immediately to mind. Separation of symmetrical from asymmetrical interaction, for example, usefully distinguishes relatively even contests from situations in which a gang or an oppressor visits violence on a victim having no means of retaliation. Whether agents of a constituted government participate in public violence, as we shall see, significantly affects its character; thus we might also classify public violence by the presence or absence of governmental agents. Again, public violence probably incorporates scale effects, so that damaging interaction involving just two or three people differs qualitatively from otherwise similar interaction involving thousands of people at a time. The present classification gives priority to coordination and salience on the hunch that those two dimensions capture a significant part of the systematic variation about which social scientists have produced useful ideas and findings.

Figure 1 Crude typology of public violence.

Within the coordination-salience space we can conveniently distinguish five locations:

1. organizational outcomes: various forms of collective action generate resistance or rivalry to which one or more parties respond by actions that damage persons and/or objects; examples include demonstrations, protection rackets, governmental repression, and military coups, all of which frequently occur with no more than threats of violence, but sometimes produce physical damage;
2. coordinated destruction: persons or organizations specialized in the deployment of coercive means undertake a program of damage to persons and/or objects; examples include war, genocide, collective self-immolation, and some kinds of terrorism;
3. opportunism: as a consequence of shielding from routine surveillance and repression, individuals or clusters of individuals use immediately damaging means to pursue generally forbidden ends; examples include looting, gang rape, revenge killing, and some sorts of military pillage;
4. fragmented resistance: in the course of widespread small-scale and generally nonviolent interaction, a number of participants respond to obstacles, challenges, or restraints by means of damaging acts; examples include sabotage, clandestine attacks on symbolic objects or places, assaults of governmental agents, and the more immediately damaging forms of what James Scott (1985) calls 'weapons of the weak';
5. violent games: two or more relatively well-defined and coordinated groups follow a known interaction script entailing the infliction of damage on others as they compete for priority within a recognized arena; examples include gang rivalries, contact sports, some election battles, and some struggles among supporters of teams or stars.

Of course these crude types overlap, for example, in the activities of the South Asian thugs who sometimes act as enforcers for landlords in disputes with squatters (organizational outcomes) but at other times follow their patrons in large-scale raids on their caste, religious, or political enemies (coordinated destruction). Similarly, the various actions known as terrorism show up in all four corners of Figure 1 – as clandestine resistance, as a by-product of peaceful claim-making in highly repressive regimes, as part of genocide, and as opportunistic elimination of old enemies. It is nevertheless useful to retain the five-part division, because within each area thus delineated social scientists have accumulated at least a modicum of systematic knowledge. Let us therefore review them one by one. The following discussion gives extensive attention to organizational outcomes and coordinated destruction, then uses analogies and comparisons with the first two as it treats opportunism, fragmented resistance, and violent games much more summarily.

Organizational outcomes. A significant share of public violence occurs in the course of organized social processes that are not in themselves intrinsically violent. That is notably the case in collective political struggle. Political regimes differ dramatically in the scope they allow for nonviolent collective making of claims, for example, by petitioning, shaming, marching, voting, boycotting, striking, forming special-interest associations and issuing public messages. On the whole, democratic regimes tolerate such claim-making more readily than do their undemocratic neighbors; that is one way we recognize a regime as democratic. Even in democratic regimes, nevertheless, such forms of collective claim-making occasionally generate open violence. That occurs for three main reasons.

First, every regime empowers agents – police, troops, headmen, posses, sheriffs, and others – to monitor, contain and, on occasion, repress collective claim-making. Those agents always have some means of collective coercion at their disposal, and always enjoy some discretion in the use of those means. In one common sequence, claimants challenge repressive agents, occupy forbidden premises, attack symbolically significant objects, or seize property, then agents reply with force. Because variants on that sequence frequently occur, when repressive agents are at hand they actually perform the great bulk of the killing and wounding that occurs in public violence.

Second, collective claim-making often concerns issues that sharply divide claimants from regimes, from powerful groups allied with regimes, or from rival groups; examples are campaigns to stop current wars, outlaw abortion, or expel immigrants. In these circumstances, offended parties often respond with counterclaims backed by force, whether governmental or nongovernmental.

Third, in relatively democratic regimes an important share of collective action centers not on specific programs but on identity claims: the public assertion that a group or a constituency it represents is worthy, united, numerous, and committed (WUNC). Assertions of WUNC include marches, demonstrations, mass meetings, occupations of plants or public buildings, vigils, and hunger strikes. Even when the means they adopt are currently legal, all such assertions entail implicit threats to direct WUNC energy toward disruptive action, implicit claims to recognition as valid political actors, and implicit devaluation of other political actors within the same issue area. These features sometimes stimulate counter-action by rivals, objects of claims, or authorities, with public violence the outcome.

Organizational outcomes also include some encounters that do not begin with concerted making of claims. Border guards, tax collectors, military recruiters, census-takers, and other governmental agents, for example, sometimes generate intense resistance on the part of whole communities as they attempt to impose an unpopular measure. Similarly, audiences at theatrical performances, public ceremonies, or executions occasionally respond collectively to actions of the central figures by attacking those figures, unpopular persons who happen to be present or symbolically charged objects. By and large, organizational outcomes connect with issues over which groups are also currently contending in nonviolent ways.

One subclass of organizational outcome, however, displays a rather different pattern. Some organizations specialize in controlling coercive means, threatening to use those means if necessary, but seeking compliance without violence if possible. Examples include not only established agents of repression but also *mafiosi*, racketeers, extortionists, paramilitary forces, and perpetrators of military coups. When such specialists in coercive means encounter or anticipate resistance, they commonly mount ostentatious but selective displays of violence. Their strategy resembles that of many Old Regime European rulers, who lacked the capacity for continuous surveillance and control of their subject populations, but often responded to popular rebellion with exemplary punishment – rounding up a few supposed ringleaders, subjecting them to hideous public executions and thus warning other potential rebels of what might befall them. The strategy is most successful, ironically, when specialists in coercion never actually have to deploy their violent means.

Coordinated destruction differs in precisely that regard. It refers to those cases where persons or organizations specialized in the deployment of coercive means undertake a program of actions that damage persons and/or objects. Coordinated destruction overlaps with organizational outcomes because specialists in coercion participate in both and because threats of force sometimes escalate into struggles between coercive organizations. Here, the organizations' strategies center, however temporarily, on the production of damage. Examples include war, genocide, collective self-destruction, public penance, and government-backed terror. The major distinctions separate (1) lethal contests, (2) campaigns of annihilation, and (3) ritual harm.

In lethal contests, at least two organized groups of specialists in coercion confront each other, each one using harm to reduce or contain the others' capacity to inflict harm. War is the most general label for this class of coordinated destruction, but different variants go by the names of civil war, guerrilla, low-intensity conflict, and conquest. Although lethal contests of various sorts stretch back as far as humanity's historical record runs, the standard image of two or more disciplined national armies engaged in destroying each other within generally accepted rules of combat only applies to a very small historical segment: roughly 1650 to 1950 for Europe, a few much earlier periods for China, even rarer intervals elsewhere in the world. Outside of those exceptional moments, autonomous raiding parties, temporary feudal levies, mercenary assemblages, bandits, pirates, nomads doubling as cavalry, mobilized villages, and similar conglomerate or part-time forces have fought most historical wars.

Lethal contests shade over into campaigns of annihilation when one contestant wields overwhelming force or the object of attack is not an organization specialized in the deployment of coercive means. Analysts have employed the term genocide for those campaigns in which attackers define their victims in terms of shared heritage and politicide for those in which victims belong to a common political category; so far no commonly accepted term has emerged for similar campaigns aimed at members of religious or regional categories. The usual stakes in campaigns of annihilation are collective survival, on one side, and recognition as the sole party with the right to territorial control, on the other. Because of those stakes, such

struggles tend to generate vast mobilizations of support extending far beyond the specialists in coercion who initiate them.

Ritual harm plays a much smaller part in contemporary public violence than do lethal contests and campaigns of annihilation. At times, however, they have assumed considerable importance, for example, in the potlatch (aggressive, competitive destruction of the performer's own symbolically charged property) that once marked struggles for precedence along America's northwest coast. Other well known instances include the processions of flagellants once organized regularly by Renaissance Italy's penitent confraternities. Today self-immolation, collective suicide, and hunger strikes occasionally occur as gestures of protest, serving chiefly to dramatize the positions of groups that lack other political resources.

Within the broad category of coordinated destruction, a remarkable change occurred during the half century following World War II. Where interstate wars among well-identified national armies had predominated for a century or more, shifts toward a much wider variety of coercive forces and toward campaigns of annihilation elevated civil war, broadly defined, to the chief setting of coordinated destruction. Decolonization, expansion of world trade in arms and drugs, reappearance of mercenary forces, and the weakening of central state capacity in many world regions all contributed to that change.

Opportunism combines low levels of coordination with high salience of violence within the total interaction. Opportunism benefits from some of the same processes that have favored recent moves away from interstate war toward violent struggle within state boundaries. Looting, gang rape, revenge killing, and some sorts of military pillage all occur more frequently in interstices, peripheries, and lapses of central state control. In fact, opportunistic public violence often occurs as an outgrowth of coordinated destruction. Disbanded but still armed troops, for example, frequently use their arms to prey upon civilians. The destruction wrought by mercenaries during truces, marches, and aftermaths of wars made them the bane of European civilian life during the sixteenth and seventeenth century heyday of mercenary armies. Similarly, when major protests or disasters divert the attention of repressive forces, looters and killers often take advantage of relaxed control to pursue their own ends.

Fragmented resistance involves segmented or weakly coordinated damage to persons or objects in the course of interactions that are not predominantly violent. When governmental agents, landlords, employers, religious authorities, or other powerful people impose innovations, exactions, or constraints on subject populations, members of those populations often resist indirectly and on the small scale. They engage in sabotage, ambushes, and clandestine attacks on symbolic objects or places, and temporary acts of resistance that either inflict damage on authorities or incite violent reprisals from authorities. Fragmented resistance differs from organizational outcomes chiefly in the balance of forces among parties and the scale of organization among the weaker parties. Otherwise, the same regularities that apply to organizational outcomes apply to fragmented resistance.

In its most stylized forms, such as the medieval tournament, coordinated destruction comes to resemble violent games. Likewise, such violent games as ritual fights between youths of neighboring villages edge over into coordinated destruction. Still, we can usefully distinguish a class of public violence in which two or more relatively well defined and coordinated groups follow a known interaction script entailing infliction of damage on others as they compete for priority within a recognized arena. Age grades of local youths, organized gangs, sports teams, supporters of powerful or popular figures, electoral factions and fraternal orders inducting new members all sometimes engage in violent games. Frequently the outcome of the contest produces confirmation or alteration of a rank order that in turn entitles winners and their followers to prestige or privilege. In that sense, violent games stand somewhere between (1) WUNC performances (whether violent or not) and (2) the public displays of wealth, power, and patronage by which warlords, crime bosses, political magnates, heads of influential families, *caciques*, and entertainment stars maintain their credibility.

In all its forms, public violence interacts closely with nonviolent politics. Violence as organizational outcome or coordinated destruction clearly entails struggles for power and takes shape from the character of power struggles spanning violent and nonviolent action. Violence as opportunism and fragmented resistance often occurs as a by-product of grand political processes: state formation, revolution, war, military conscription, taxation, and patron–client realignment. Violent games follow their own rules, but frequently intersect with or mutate into other forms of public violence. At first glance, violence may seem the antithesis of orderly public politics. At second glance, most public violence connects closely with politics in general.

Virtual Reality and Spatial Cognition

Abstract

In this article, the significance of virtual reality within the field of spatial cognition is outlined. The role of virtual reality is grouped in three sections addressing (1) the current and latest technology of virtual reality regarding the two main functions within virtual reality, that is, technology to interact with virtuality (input devices used to record observer actions and output devices used to simulate sensory stimuli) and technology for presenting the virtual environments to the user, (2) the usage of this technology for the purpose of research in the field of spatial cognition regarding behavioral and neuronal processes (discussing advantages and disadvantages of virtual reality), and (3) virtual reality experiments and their results that are relevant in current research of spatial cognition covering place memory, wayfinding in large-scale spaces, and the neural representations of spatial features.

The term 'virtual reality' was first used and introduced by Jaron Lanier in 1989. By definition, virtual reality is a collection of technologies for generating a human–computer interface that allows people to interact efficiently with, become immersed in, and to feel the presence in computerized 3D environments, while using their natural senses and motor skills in real time. Here, immersion refers to the technical capability of the system to deliver a surrounding and convincing environment with which the user can interact. Presence is the sense of being (embodied) in a virtual environment rather than in the physical space where the real user's body is actually located.

During the last years, computer technology has improved substantially and with it the factors supporting immersion and presence. Improvements concern the complexity and richness of the details of the virtual environments displayed or the diversity and fidelity of sensory and motor interactions involved in the virtuality. The following sections will address these advancements and discuss their application within the field of spatial cognition.

The Technology of Virtual Reality

Virtual reality is largely based on computer graphics. The quality of computer graphics increased substantially within the last years affecting features such as the size of virtual environments, their level of detail, the realism of surface texture, the modeling of illumination, shading and shadowing, and the animation of objects and avatars. At the same time, the fidelity of sound and the speed of rendering (i.e., the process of computing a 2D image from a 3D database) have improved. Through these advancements, virtual environments are now able to closely approximate real world conditions. As a result of a development mostly driven by the computer game industry, graphics engines are now frequently available as open-source software (e.g., Unreal Engine 3, CryENGINE 3, OpenSceneGraph, and Ogre3D) and run on cheap, custom hardware with satisfactory results, that is, engines enable rendering of and allow interactions with virtual environments in real time and in a highly realistic manner.

In terms of interaction with virtual environments, users can rely on classical devices like the computer mouse, joystick, and gamepad (Figure 1(a)) to act in the virtual space. In addition, a large number of more sophisticated devices have been developed for special purposes. The flystick is an extended joystick where the position is tracked in six degrees of freedom (Figure 1(b)). The Phantom® device combines position sensing of a single finger with force feedback to that finger to create a closed loop of haptic interaction. Motion capture with devices such as the Kinect controller (Microsoft®) is now common even in the consumer market. High-precision motion capturing of the head, the hand (e.g., data glove; Figure 1(c)), or the whole body allows the use of real body movements to alter the viewing direction, to manipulate objects, to change the body position, or to do all these actions together in the virtual reality. Furthermore, body capturing can be used to animate an avatar (a virtual agent), usually a person who is visible within a virtual environment and can interact with it. Movement devices such as the VirtuSphere (Figure 1(d)) or the omnidirectional 'Cyberwalk' treadmill (Figure 1(e)) allow users to walk for unlimited distances within a virtual environment thus expanding the physical limitations of a restricted tracking space in laboratory rooms. Furthermore, such movement devices facilitate the sense of real walking and provide movement tracking at the same time, which is a combination hard to realize in reality.

Concerning visual stimulation, today a huge number of devices are available that allow the presentation of virtual sceneries to the user. In most cases stimuli are presented on flat desktop screens, covering just a restricted part of the human field of view. Usually, users have to rely on a mouse or a keyboard to interact. A more direct interaction becomes possible when using head tracking together with a head mounted display (Figure 1(a)). In a head mounted display, stimuli are presented by the use of two small LCD screens placed in front of the eyes in order to interlink real head movements with rotations and translations in the virtual world. Such head mounted displays are also applied when walking on treadmills or in walking spheres (see above). Stimulating the entire field of view of

Figure 1 Devices for interacting with and presenting of virtual environments. (a) Subject is using a gamepad to interact within a virtual environment presented via head mounted display (from Max Planck Institute for Biological Cybernetics, Tübingen). (b) Flystick to interact in all possible degrees of freedom. (c) Data glove to control the movement of a virtual hand. (d) Subject is walking in the VirtuSphere (from Cognitive Neuroinformatics, University of Bremen). (e) Subject walking on the omnidirectional 'cyberwalk' treadmill (from Max Planck Institute for Biological Cybernetics, Tübingen; http://www.cyberwalk-project.org/).

a human subject requires large projection screens (curved or flat; Figure 2) or the combination of such multiple screens in a so-called Cave. Furthermore, stereoscopic stimulation can increase the feeling of immersion by providing realistic binocular depth cues. Stereoscopic 3D effects are produced by means of head mounted displays, anaglyph glasses, shutter glasses, polarization glasses, or by special 3D displays.

The Application of Virtual Reality in Spatial Cognition

In the field of spatial cognition, researchers investigate behavioral and neuronal processes associated with the perception, representation, revision, and utilization of knowledge about spatial environments or conditions and the behaviors bearing on such knowledge. Spatial knowledge is apparently associated with locations of something in relation to a spatial reference. Research on behavior attainments focuses on orienting in spatial layouts, homing (i.e., the ability to find the way back to a certain home place), pointing toward goals in an environment, extracting visuospatial information by head and eye movements, navigating in large-scale (urban or cluttered) environments or mazes, and the communication about spatial facts. Concerning neuronal processes, questions about brain areas involved in spatial cognition, the representational format as well as the metrics of spatial codes, the involvement of different senses (i.e., multisensory processing), and the characteristics of spatial features crucial for spatial behavior are examined.

Spatial cognition research is often closely related to virtual reality technology. In fact, for the majority of research questions, the simulation of spatial conditions is a requirement that at least substantially simplifies the experimental procedures. Imagine a navigational experiment where subjects have to find certain routes within a town or another large-scale terrain. Here, it would be hardly possible to ensure repeatability in a highly controlled manner when performing such a task in a real urban environment. Furthermore, manipulations of the spatial layout or metrics, objects within the scenery, or the sensorimotor processing cannot be realized. Consequently, spatial cognition profits greatly from the advancements in virtual reality technology:

1. Virtual reality is highly controllable and makes procedures repeatable with respect to the design of the environment and the way of interacting with it.
2. Body position, pointing direction, and exploration movements can be measured with high precision in real time.
3. Manipulations of the environment, of viewpoints or metrics of the virtual space (e.g., physical inconsistencies or non-Euclidean metrics), and of interactions with the virtual reality are possible in real time.
4. Different sensory modalities related to spatial perception can be tested selectively and can be brought into competition with one another in order to estimate their relative contributions for a given task.
5. Virtual reality enables the measurement of spatial behavior in large-scale environments also under real walking conditions (e.g., treadmill or walking sphere).
6. Virtual reality enables recordings of neuronal activities during spatial performance (e.g., by use of EEG or fMRI). Single or multicell recordings are done in rats or mice using an adapted version of the walking sphere (Hölscher et al., 2005; Figure 4).
7. Experiments in the real space may be inappropriate or impossible because of inaccessibility, cost, excessive danger, security requirements, etc. These limitations can be bypassed when using virtual reality.

On the other hand, virtual reality entails some disadvantages or attentions the user must take into consideration. Cyber- or simulator sickness is one of them (Stanney et al., 1998). It can be caused by temporal interrupts or delays in the interaction and stimulation due to hard- or software processes or by cross-sensory conflicts between vestibular and visual stimuli. For example, the perception of self-movement (vection) can be induced purely visually without stimulating the vestibular or the proprioceptive system, yielding a conflict that might result in simulator sickness. The symptoms of this sickness include disorientation, disequilibrium, drowsiness, salivation, sweating, and vomiting. Another aspect when using virtual reality is the conflict between the virtual and the physical reality. Both environments might be represented partially at the same time and generate conflict between each other, for example, when a virtual and a real room differ in orientation (May, 2004). Just like with simulator sickness, the amount of disturbance will depend on the used setup and the task at hand.

In virtual reality, the user is always confronted with virtual stimuli, generated by a certain technology to simulate the reality. The degree of realism in virtual reality as well as the way of presentation and interaction has to be chosen with respect to the scientific question or the kind of task to investigate. Hence, experimenters need the knowledge about the range of possibilities when simulating real conditions. Additionally, when applying virtual environments, the user needs a certain amount of training to get familiar with the simulated realism. Setups for virtual reality can also be very expensive and need a high amount of engineering power for successful running (e.g., Cave or treadmill setup).

Spatial Cognition: Experiments in Virtual Reality

Virtual reality is applied in various research areas including spatial cognition. The following experiments in human and animal navigation will show how virtual reality can contribute to examining such a field. These examples address (1) the contribution of different information sources, (2) the selection of environmental features, and (3) the neuronal implementation in the brain.

Virtual reality can help to identifying whether humans integrate and memorize their paths walked and/or rather rely on visual information such as landmarks (i.e., environmental, salient objects that are easy to recognize) encountered. Foo et al. (2005) had participants physically walk through a hall while displaying a virtual environment to them via a head mounted display. When putting spatial information derived from paths walked before and visual landmarks into conflict, participants heavily relied on visual landmarks and tended to ignore conflicting body information. So in the case of conflict, humans identify locations visually rather than use on body-based information. However, body cues do contribute in addition to visual information as well. Ruddle et al. (2011) compared walking through a large-scale space on an omnidirectional treadmill with navigating the same space only visually. Participant's direction and distance estimates to remote locations profited from physical walking distances within the environment, but not from physical rotations alone as compared to navigating only visually. Although humans do rely mainly on visual information,

body-based cues especially traversing distances contribute to our memory as well.

If vision is important, which features of the visual information are used by navigators? Steck and Mallot (2000) displayed local and global landmarks (i.e., houses and mountains) on a screen covering 180° of the horizontal field of view. Participants memorized both types of landmarks using them to retrace a route when the one or other type was absent. When putting local and global landmarks into conflict (by displacing the global ones) participants showed quite individual preferences. Stankiewicz and Kalia (2007) had participants navigate through a virtual maze with certain objects and intersections appearing rarely or more often. Subjects relied more strongly on landmarks that were more salient or specific. Structural landmarks such as walls were valued higher than object landmarks. Humans seem flexible with respect to which visual information to use. In general, they focus on informative landmarks and on the surrounding geometry. Gillner et al. (2008) used virtual reality to generate an environment where smooth color distributions provided the sole cue to position while features and objects that could have provided landmark information were absent. Still, subjects were able to home and recognize places, indicating that a simple, 'snapshot-matching' mechanism of place recognition is available to humans.

Virtual reality can not only be used to examine newly learned spaces. Frankenstein et al. (2012) asked inhabitants of Tübingen to point to locations within a photorealistic model of their hometown (virtual Tübingen; Figures 2 and 3). Participants performed the more accurately the more closely they were facing north within virtual Tübingen and their pointing performance did not differ at all for close-by and far away pointing targets. This indicates that spatial memory within their hometown was acquired from maps and combined with a different source of information, namely navigation-based information in order to point from within an environment.

Virtual reality is also highly suited to examining the neural basis of location memory and navigation. This is, for example, done by measuring brain activity during moving through a virtual environment. In an early study, Maguire et al. (1998) showed that visual navigation as compared to simply following an indicated path is associated with activity in parietal areas and the hippocampus. The more directly navigators approached a familiar route the higher was the hippocampal activity. Wolbers and Büchel (2005) showed that the integration of locally experienced views within a virtual environment is paralleled by increased hippocampal activity. Hippocampus is involved in relating multiple views; other regions are involved in different aspects of navigation. Janzen and Weststeijn (2007) showed that the relevance of landmarks (i.e., whether they were located at decision points or at nondecision points) is processed in the parahippocampus, whereas the processing of route order is related to various other structures, for example, parietal areas.

Virtual reality is not limited to humans. Dombeck et al. (2010) as well as Hölscher et al. (2005) had rats walking a movable sphere while displaying their progression visually (Figure 4). Then they measured electric currents in implanted electrodes within the hippocampus and identified so-called place cells that code for a certain location within the space (O'Keefe and Dostrovsky, 1971). This shows that even animals react toward a virtual reality in a way they behave within real environments.

The examples show how virtual reality can be fruitfully used within spatial cognition research. Despite some disadvantages such as the occurrence of simulator sickness, virtual reality allows for highly realistic stimulation while at the same time keeping full experimental control. With the technology further improving and especially becoming cheaper and more easy to use, virtual realities will also become more widespread not just within spatial cognition research.

Abstract

Virtual reality (VR) provides a new medium for the presentation of emotionally relevant, complex stimuli in an ecologically valid and at the same time highly controlled manner. Therefore, VR applications have attracted the attention of psychotherapists and researchers. In the past years, viable VR systems for varied applications in psychotherapy have been developed, most notably for exposure therapy in anxiety disorders. This article resumes the major applications of VR in psychotherapy, gives an overview of the current literature on its efficacy, and provides an outlook on future perspectives for psychotherapy and clinical research.

Virtual reality (VR) is a computer-generated presentation that differs from common video or audio technology by its interactive nature. VR aims for the greatest possible immersion in order to create in the user a sense of presence in the virtual environment. To achieve this, VR systems provide input to the user's sensory channels and replace sensory input from the real world. The user views the VR environment via a head-mounted display (HMD; **Figure 1**) or large projection screens (CAVE system; **Figure 2**). Besides, most VR systems also provide auditory input, and input of other modalities like olfactory and haptic stimulation is also possible. Importantly, the computer system that controls the VR presentation receives user information through sensors and/or input devices, e.g., head tracking systems, joystick, buttons, or a personal computer mouse. Adapting the VR environment in real time, the computer enables the user to experience the illusion of being in the virtual world. Both user and VR system receive mutual feedback, making the system truly interactive.

VR systems were first used for simulator training in aviation, spaceflight, or for military purposes. In these applications, VR enables users to learn how to operate a complex technical system in a risk-free simulation, before applying their skills to the real, often dangerous machinery. In clinical psychology, VR has attracted attention for its potential to create an emotional experience and to instigate processes of emotional learning, which lie at the heart of psychotherapy. Today, VR technology is used in a fast-growing number of applications in clinical research and therapy, particularly as a form of exposure therapy for anxiety disorders called virtual reality exposure therapy (VRET). The history of VR therapy is summarized in **Box 1**.

Exposure Treatment: A Standard Technique in Cognitive Behavioral Therapy for Anxiety Disorders

State-of-the-art cognitive-behavioral therapy for anxiety disorders includes *in vivo* or in *sensu* exposure treatment. After cognitive preparation (including psychoeducation), patients are encouraged to overcome their avoidance behavior and to confront the feared objects or situations in real life or in their imagination until a reduction of subjective and physiological symptoms of anxiety occurs. *In vivo* exposure is especially effective: Response rates of up to 80–90% have been reported in randomized-controlled trials (Choy et al., 2007).

Probably the most influential theory about the processes underlying the efficacy of exposure therapy was provided by Foa and Kozak (1986). Their emotional processing theory postulates that irrational fear may be conceptualized as a 'fear network' that links the anxiety-provoking stimuli with cognitive (e.g., evaluation as threatening), emotional (subjective experience of fear and anxiety), physiological (e.g., increase in heart rate), and behavioral (e.g., avoidance) responses. According to Foa and Kozak (1986), exposure therapy works by altering this fear structure. Information elements that are incompatible with the fear structure, e.g., the information that the feared consequences do not occur, are incorporated into the fear structure. Emotional processing theory also considers psychophysiological arousal a necessary first step in exposure therapy, as arousal indicates that the fear structure has been activated and is thus accessible to change.

Virtual Reality Exposure Therapy

While the high efficacy of *in vivo* exposure therapy is well documented, in practice many obstacles and problems with this form of therapy remain. Major drawbacks of *in vivo* exposure are its time-consuming nature and the difficulty of creating relevant exposure situations for many anxiety disorders (e.g., social anxiety disorder, agoraphobia, and posttraumatic stress disorder (PTSD)) (Mühlberger and Pauli, 2011). VR offers an alternative medium for conducting exposure therapy. As an emerging alternative, VRET might help to overcome these obstacles. VRET has been tested for most anxiety disorders, including specific phobia, panic disorder and agoraphobia, PTSD, and social anxiety disorder (Bouchard et al., 2007). For generalized anxiety disorder and obsessive–compulsive disorder, few studies exist so far.

Advantages and Limitations of VRET

VRET offers a range of advantages that make this technique attractive for mental health professionals. The 'gold standard'

Figure 1 Basic components of a VR system as used at the University of Regensburg, Germany.

Figure 2 Driving environment in the PsyCAVE at the University of Würzburg, Germany. Reproduced from Mühlberger, A., 2014. Virtuelle Realität in der Klinischen Emotions- und Psychotherapieforschung. In: Jeschke, S., Kobbelt, L., Dröege, A. (Eds.), Exploring Virtuality, Springer, Berlin/Heidelberg.

in exposure-based treatment, *in vivo* exposure, is often time-consuming, costly (e.g., in aviophobia), and requires a great deal of preparation on the side of the therapist in order to provide the necessary stimuli or create the situation that is needed. These factors limit the availability of exposure-based treatment. As a result, many patients who would benefit from this form of therapy do not receive exposure therapy at all. VRET offers an alternative that can take place in the therapist's office. Relevant exposure elements can be repeated effortlessly as many times as needed. For some anxiety disorders, especially PTSD, *in vivo* exposure to the relevant stimuli may be dangerous, or impossible. Therapists often rely on their patients' imagination to recreate the relevant experience from their memory, a task that is inherently difficult for most patients suffering from PTSD. Here, VRET not only provides a medium to present relevant environments to recall and confront traumatic memories, but also helps the therapist to pace the exposure process and to keep control of its gradual progression.

In general, due to high levels of apprehension and avoidance, many patients with anxiety disorders do not seek treatment, or drop out of treatment. There are indications that patients might accept VRET more easily than standard *in vivo* exposure. García-Palacios et al. (2007) found that of a mixed

Box 1 History of VR therapy

Already in the 1960s, foreseeing the potential of computer technology, Sutherland conducted first experiments with a still cumbersome HMD that was hung from the ceiling (Sutherland, 1968). This display could project simple three-dimensional structures. It was already equipped with a sensor that recorded head movements of the user, and the display was updated using this information. Before VR technology was ready for clinical applications, it was used mainly for training purposes, especially in aviation, spaceflight, and for military purposes. The first publications on VR as an exposure technique for specific phobia date back to the 1990s. Since then, the developments of interactive computer graphics in the field of PC games have led to a fast-developing range of applications. Apart from clinical psychology and psychotherapy, VR scenarios are also increasingly used as aids to motor rehabilitation for patients suffering from neurological disorders.

patient group (64.7% specific phobia, 35.3% social phobia; $n = 150$), 76% preferred VRET over *in vivo* exposure. About 27% indicated they would refuse *in vivo* exposure therapy, while just 3% reported they would reject VRET. Further, the highly controllable setting makes the processes that occur during VRET accessible to researchers; self-reported, behavioral, and physiological levels of anxiety can be assessed online. Thus, VR technology is a promising research tool, too. **Box 2** summarizes the advantages of VRET.

Limitations of VRET include technological and clinical barriers. VR systems may provoke simulator sickness, characterized by symptoms like nausea, visual strain, headache, and dizziness. Simulator sickness resembles motion sickness, and is related to a mismatch between sensory, proprioceptive, and vestibular information (e.g., a user is moving visually through a VR environment, but is physically standing still). However, severe simulator sickness is rare. In fact, fewer than 5% of the patients discontinue VRET due to simulator sickness. Another obstacle is that some patients do not experience considerable anxiety during VRET; however, whether this affects treatment outcome has not been investigated yet. Because of limited empirical data, VR researchers suggest that patients with difficulties to differentiate between real events and fiction, e.g., patients with symptoms of acute psychosis, should not receive VR-based treatment, and psychosis is commonly defined as an exclusion criterion in studies (e.g., Gorini et al., 2010). Interestingly, recent preliminary studies hint at a positive effect of VR skills training for patients with psychosis (Kurtz et al., 2007; Park et al., 2011; see below). Thus, further research might lead to a revision of this limitation and individually tailored VR treatments might be useful even in those patients after careful consideration of the individual case and symptoms. An important limitation for the clinician is the lack of commercially available software packages for conducting VRET. So far, researchers have relied heavily on shareware solutions that are restricted to a small selection of fears or require varying degrees of programming skills. We expect, however, that appropriate software solutions will appear on the market soon, making VRET available to clinicians on a large scale. Additionally, new hardware developments (e.g., cost-effective HMDs with large field of view) will enhance presence, reduce side effects, and promote the application of VRET.

VRET for Specific Phobia

By its nature, VRET is most easily applicable to anxiety disorders with distinctive phobic stimuli, which can be readily implemented in a VR environment, as is the case for specific phobia. VRET has been applied most often to aviophobia, acrophobia, and arachnophobia. Other, more complex stimuli, like virtual humans (agents) for VRET of social phobia are more difficult to render in VR. It is therefore not surprising that specific phobia has been the first and most intensely studied disorder in VRET research. For an example of VR therapy for tunnel phobia, see **Box 3**.

VRET for Aviophobia

In vivo exposure for aviophobia commonly includes at least one commercial flight, making this treatment rather costly for the patient. Here, VRET offers some specific advantages over *in vivo*

Box 2 Advantages of VRET

- Cost-effectiveness (especially for aviophobia and driving phobia).
- Less effort in organizing exposure sessions (especially for agoraphobia and social phobia).
- Confidentiality and safety.
- Exposure may be repeated easily.
- Specific stimuli (e.g., turbulence) may be implemented and presented repeatedly as needed.
- Type, intensity, and duration of exposure are entirely controlled by the therapist.
- Patients' reactions may be observed and recorded.
- Patients may be motivated more easily to try out new behavior.
- High patient acceptance and low threshold for seeking treatment.
- Patients lacking in imagination may be treated more effectively than with imaginal exposure.
- The laboratory setting makes VRET easily accessible for research.

Box 3 Example case: VRET for tunnel phobia

Before therapy, Ms. W. suffered from intense fear of tunnels. The treatment consisted of four sessions over the course of 6 weeks. After cognitive preparation, Ms. W. was exposed to repeated tunnel drives in VR. During the first session, Ms. W. reported that she experienced strong anxiety and found herself unable to look at anything except the road straight ahead of her. Her breathing was shallow, her palms were sweaty, and her heart rate was accelerated. In the second session, the therapist started to slow down the drive through the tunnel, and introduced breaks in the tunnel. Ms. W. was encouraged to try behaviors she had long avoided, like looking around in the tunnel. At first, this elicited intense fear, but this anxiety subsided gradually. By the fourth session, the drive through the tunnel no longer triggered anxiety, breathing had normalized, and Ms. W. was able to look around in all directions without experiencing fear. After therapy, Ms. W. was able to drive through real tunnels. She also found herself to be much more relaxed handling her own anxiety in different situations. No return of fear while driving through road tunnel was reported even 2 years after treatment.
(Adapted from Mühlberger, A., Pauli, P., 2011. Virtuelle Realität in der Psychotherapie. (Virtual reality in psychotherapy). PiD - Psychotherapie im Dialog 12 (2), 143–147 with permission.)

exposure. First, VRET allows exposing patients to as many flights as necessary at little cost. Further, the most feared aspects of flying for aviophobic patients are usually takeoff and turbulence. In VRET, these specific flight phases can be manipulated and repeated many times. For example, a motion platform to effectively simulate turbulence is used, which is found to have a marked effect on self-reported fear and physiological indicators of arousal (Mühlberger et al., 2005)(see Figure 3). A simpler and cost-effective technological solution that nonetheless has been proven to be effective is the use of subwoofers to simulate airplane movements and provide haptic stimulation. Overall, numerous studies have investigated the efficacy of VRET for aviophobia, with very good results (for a review, see da Costa et al., 2008). Wiederhold and Wiederhold (2003) reported on stable effects of VRET for aviophobia at follow-up after 3 years.

Figure 3 Flight simulator as used at the University of Würzburg, Germany. Reproduced from Mühlberger, A., 2014. Virtuelle Realität in der Klinischen Emotions- und Psychotherapieforschung. In: Jeschke, S., Kobbelt, L., Dröege, A. (Eds.), Exploring Virtuality, Springer, Berlin/Heidelberg.

VRET for Acrophobia

One of the earliest and most impressive studies on the efficacy of VRET was conducted by Emmelkamp et al. (2002) for acrophobia. Emmelkamp et al. (2002) directly compared *in vivo* exposure with VRET and therefore reproduced the actual *in vivo* exposure settings in the VR environment (e.g., looking down from a gallery in a shopping mall). The randomized-controlled study revealed VRET to be equally effective as *in vivo* exposure. Importantly, comparable treatment effects were found not only for ratings of fear, but also in a posttreatment behavior avoidance test conducted *in vivo*. Thus, VRET effects were successfully transferred to the real world. Treatment effects were further found to be stable after 6 months in both the groups. Since then, many studies have confirmed the efficacy of VRET for acrophobia (Meyerbröker and Emmelkamp, 2010). Unfortunately, direct comparisons between VRET and *in vivo* exposure are still rare. Figure 4 depicts VR scenarios used for the treatment of specific phobias.

VRET for Phobia of Small Animals

A number of studies have investigated VRET for arachnophobia, with positive results (e.g., Côté and Bouchard, 2005). Figure 5 shows the reduction of fear within and between sessions of VRET for arachnophobia (Shiban et al., 2013). An interesting development of VRET that has been applied to the phobia of small animals is augmented reality. An augmented reality system makes use of a transparent HMD to project images of feared objects onto the real-life environment. This way, patients may encounter and may be exposed to virtual spiders, cockroaches, or other small animals superimposed on the real environment, e.g., the therapy room, while they can see their own body in this environment. Thus, this technology also allows seeing the feared animals crawling across the own body (Juan and Calatrava, 2011). Arachnophobia is also frequently used as

Figure 4 VR scenarios for the treatment of phobias. Reproduced from Mühlberger, A., 2014. Virtuelle Realität in der Klinischen Emotions- und Psychotherapieforschung. In: Jeschke, S., Kobbelt, L., Dröege, A. (Eds.), Exploring Virtuality, Springer, Berlin/Heidelberg.

a paradigmatic anxiety disorder in VR research aimed at dismantling processes of anxiety and anxiety reduction (e.g., Diemer et al., 2013; Shiban et al., 2013; see below).

VRET for Other Specific Phobias

Other specific phobias that have been treated with VRET include fear of driving and fear of tunnels. The specific advantages of VRET for these phobias include safety and convenience. As is the case in aviophobia, the phobic situation may be prolonged and repeated as many times as needed. **Figures 2** and 4 present VR environments used in VRET for driving and tunnel phobia.

Figure 5 Fear reduction during VRET for arachnophobia. Subjective fear ratings at the start and end of each of four sessions are shown.

VRET for Other Anxiety Disorders

VRET for Posttraumatic Stress Disorder

Another important application of VRET is the treatment of PTSD. Several studies have been conducted, especially for combat-related PTSD and PTSD in survivors of terrorist attacks. Military personnel are at an increased risk for developing PTSD and related disorders. One of the first studies on VRET for combat-related PTSD was provided by Rothbaum et al. (2001), with positive results. In recent years, the US military has begun a series of investigations in an effort to establish and provide appropriate treatment. This effort comprises studies on the efficacy of VRET for combat-related PTSD (Rizzo et al., 2011). Virtual scenarios replicating Iraqi and Afghan environments have been developed and tested. These scenarios include a range of visual, auditory, haptic (vibrations), and olfactory stimuli that can be employed in an individualized treatment protocol (see Cukor et al., 2009). In 2010, McLay et al. reported the first use of VRET in a military camp in the actual conflict area where soldiers were engaged in combat. Future perspectives in this area include studies on the usefulness of VR as a diagnostic tool that might help to identify individuals at an increased risk for PTSD, in order to improve assessment of fitness for duty, i.e., resilience (Rizzo et al., 2011). In the civilian field, VRET has been used to treat survivors of terrorist attacks (Difede et al., 2007) and motor vehicle accidents (Beck et al., 2007).

VRET for Social Anxiety Disorder

Social anxiety disorder is characterized by fear and apprehension of situations involving social interaction and/or social performance. Since social interactions are still difficult to create in a meaningful and believable way in VR, most VRET studies on social anxiety disorder so far have focused on the fear of public speaking, which is very common in patients suffering from social anxiety disorder. First results of VRET for fear of public speaking revealed positive outcomes (see Pull, 2012). Researchers have also found that patients respond differentially to virtual audiences, depending on the behavior of the agents in the audience (friendly vs hostile) (Pertaub et al., 2001). The development of more realistic computer-generated simulations of human

behavior (artificial intelligence) promises sophisticated future applications. Already, investigators have successfully simulated complex social interactions like small talk (Pan et al., 2012). The application of simulated humans in different forms of social interactions for exposing and training patients suffering from social anxiety disorder might be the next development in this field.

VRET for Panic Disorder and Agoraphobia

Another anxiety disorder that is increasingly treated with VRET is panic disorder with agoraphobia. Like individuals suffering from social anxiety disorder, agoraphobia patients fear various and many rather complex situations. Nonetheless, some common agoraphobic situations, like public transport, shopping centers, and tunnels have been realized in VR to treat agoraphobia patients successfully (Botella et al., 2007). With regard to panic symptoms, first results indicate that symptom simulation in VR (e.g., blurred vision) might be a promising addition to VRET for panic disorder with or without agoraphobia (Botella et al., 2007).

VRET for Obsessive–Compulsive Disorder and Generalized Anxiety Disorder

Little research exists on VRET for generalized anxiety disorder and obsessive–compulsive disorder, most likely because the feared stimuli in these disorders are very individual and because cognitive processes might play a greater role than in other anxiety disorders. Nonetheless, VR applications for these disorders have been tested (Gorini et al., 2010; Kim et al., 2009) and shown positive results. However, more research in these areas will show up soon.

Efficacy of VRET

Until 2012, four meta-analyses on the efficacy of VRET for the anxiety disorders had been published (Gregg and Tarrier, 2007; Powers and Emmelkamp, 2008; Parsons and Rizzo, 2008; Opris et al., 2012). In general, the results are promising, with large effect sizes. For example, Opris et al. (2012) report an average weighted effect size (across the anxiety disorders) of $D = 1.12$ for the comparison with wait-list control groups, while no significant differences were found between cognitive-behavioral therapy with *in vivo* exposure and VRET. However, these results are still based on a limited number of studies, with just $n = 21$ VRET studies reviewed by Opris et al. (2012). Of these, only 11 studies carried out a direct comparison of VRET with *in vivo* exposure (Opris et al., 2012). Looking at specific anxiety disorders, most research is available on aviophobia and acrophobia. For these disorders, VRET may already be considered an empirically justified treatment (Meyerbröker and Emmelkamp, 2010). More efficacy studies, especially randomized-controlled trials that include *in vivo* or imaginal exposure as control treatments, are necessary to test the efficacy of VRET for other anxiety disorders and in comparison to other interventions.

VR Applications for Other Mental Disorders

Apart from exposure treatment, VR scenarios have been developed and examined for a range of applications. One is the use of VR worlds because of their distracting potential for pain management during painful medical procedures. Hoffman et al. (2011) report pain reductions of 35–50% when patients treated for burn injuries engaged during treatment in an interactive VR game (medication + VR) compared to a medication only condition. Comparable effects were observed in patients experiencing severe pain. VR scenarios are also tested as a tool to enhance (social) learning in autistic children. First results are positive (for a review, see Beelani et al., 2011), but more research is needed. Other applications in psychotherapy are the use of VR in eating disorders, substance-related disorders, and schizophrenia.

Therapeutic Uses of VR for Eating Disorders

Body dissatisfaction, in combination with a distorted body image, is a central feature of eating disorders. VR scenarios have been created that allow patients to adapt a three-dimensional virtual body to their body image, and to compare this to their actual and desired body shapes, helping patients to realize and change the distorted nature of their own body image (Ferrer-García and Gutiérrez-Maldonado, 2012). First studies have used these VR body image scenarios in conjunction with cognitive therapy for the treatment of eating disorders, with positive results especially on measures of body satisfaction (Ferrer-García and Gutiérrez-Maldonado, 2012). Other VR scenarios for eating disorders including emotionally significant environments related to food and body image are being developed; however, little research has evaluated this approach so far.

VR Applications in Substance-Related Disorders

The main VR application for substance-related disorders is the use of VR scenarios for cue exposure. VR environments equipped with substance-related cues have been found to elicit craving in alcohol-dependent patients (Lee et al., 2009), and in users of cocaine (Saladin et al., 2006). Repeated cue exposure in VR has been reported to reduce craving in alcohol-dependent patients (Lee et al., 2009). In an ingenious, randomized-controlled study ($n = 91$), Girardi et al. (2009) found that crushing cigarettes in VR reduced nicotine addiction as assessed with a questionnaire and improved rates of abstinence and adherence to a treatment program that was delivered alongside the study. These results indicate a possible therapeutic application of VR for habit reversal.

VR-Assisted Therapy for Schizophrenia

Researchers have highlighted a number of different therapeutic VR applications for patients suffering from schizophrenia. Deficits in social interaction are central to schizophrenia and require special attention from researchers and clinicians, as the social withdrawal associated with negative symptoms of schizophrenia accounts for much of the social and occupational impairments experienced by patients. In 2011, Park et al.

published promising results of a randomized-controlled trial ($n = 91$) comparing VR-assisted vs traditional social skills training. The authors found VR role plays to be associated with greater motivation and better outcome in terms of assertiveness and conversational skills, while the *in vivo* role playing group showed better outcome on one measure only (nonverbal communication). Surely these results warrant replication and further study. Another area that has been explored with VR is medication management (Kurtz et al., 2007). Freeman et al. (2008) suggest further applications of VR as a part of a cognitive treatment program including psychoeducation, behavioral experiments, and coping with psychotic symptoms.

VR as a Research Tool

VR enables researchers to put patients into complex, yet standardized scenarios. Consequently, VR has numerous and varied applications not only as a research tool in clinical psychology, especially in therapy research, but also in assessment and basic research on the processes underlying different psychopathologies. In most of these areas, research has just begun, but we expect this area to expand considerably in the near future.

VR for Research on Therapy Processes

VR brings a form of exposure therapy into the laboratory that is far more suitable than the traditional forms of exposure for the assessment of the processes that make exposure-based psychotherapy work. For example, several studies have investigated psychophysiological parameters of treatment processes during VRET. Diemer et al. (submitted for publication) recently reviewed this field of research and found clear indications that VR exposure is accompanied by marked psychophysiological arousal, while psychophysiological habituation processes during VRET are still poorly understood. This seems to be related to the great heterogeneity of study designs used in VRET research, and the still low numbers of studies on therapy processes during VRET. In a study exploring context effects of exposure therapy, VR scenarios were used to demonstrate that exposure in multiple contexts improves the generalization of VRET treatment effects to the real word, presumably by reducing the renewal of fear (Shiban et al., 2013).

An important aspect of VR applications in psychotherapy is the concept of presence. Presence is usually defined following Slater and Wilbur (1997) as "the sense of being in the virtual environment" (see also Schubert et al., 2001). Presence is supposed to be the mediator that allows an artificial VR environment to engage real emotions (Parsons and Rizzo, 2008). As Schubert et al. (2001) have shown, presence is in fact a multifaceted construct that can be divided into three aspects: spatial presence, i.e., 'the sense that we are located in and act from within the virtual environment'; involvement, i.e., 'the attention dedicated to the virtual environment'; and realness, i.e., 'the perceived verisimilitude of the virtual environment.' Research on the significance of presence and its facets for VR therapy is underway. As Price et al. (2012) could show in a VRET study of social phobia, different components of presence may be related to different aspects of treatment.

VR for Assessment

As VR allows a direct, continuous, and unobtrusive observation of symptoms and problematic behavior (e.g., phobic avoidance), VR scenarios provide a tool for improving diagnostic accuracy. For example, Mühlberger et al. (2007) have shown that physiological responses in a VR tunnel scenario reliably differentiate tunnel-fearful from nonfearful participants. Similarly, Sorkin et al. (2006) demonstrated that performance in a VR maze differentiated patients with schizophrenia from healthy controls. Freeman et al. (2008) review a number of other VR applications for schizophrenia, including the assessment of paranoid thinking in a social situation. Other investigators have used VR scenarios to assess emotion recognition deficits in schizophrenia (Dyck et al., 2010). For attention-deficit hyperactivity disorder (ADHD), the work group of Rizzo developed a VR classroom. An attention test delivered in this VR scenario, which incorporates typical distractors, was shown to differentiate better between children affected by ADHD and controls than standard measures (Adams et al., 2009). One step further is the use of VR to monitor and gauge treatment effects. This was done by Pollack et al. (2010), who measured the effects of methylphenidate on the performance of children with ADHD in a continuous performance task in a VR classroom simulation.

VR Research on Psychopathological Processes

Adding a level of complexity to laboratory research that was previously impossible, VR is increasingly used to investigate psychopathological processes in different disorders. The research program outlined by Freeman et al. (2008) on the use of VR scenarios to identify correlates and predictors of psychotic symptoms is one approach that falls into this category. Already, VR has been used in conjunction with electroencephalography (EEG) (Lee et al., 2009) to discover neurophysiological correlates of craving in alcohol dependence. In basic research on fear and anxiety, a VR paradigm that is increasingly used combines fear conditioning with complex VR scenarios, allowing the assessment of context-conditioning and related variables. For example, Glotzbach-Schoon et al. (2013) assessing context-conditioning in a VR paradigm comparing the effects of predictable and unpredictable aversive events in participants high vs low in trait anxiety. While both groups showed contextual fear conditioning, high trait anxious subjects were found to associate the context with the aversive events especially rapidly. This research may help shed light on the processes underlying the acquisition of dysfunctional anxiety.

Further, anxiety-provoking VR scenarios can be used as a nonpharmacological challenge procedure to elicit and investigate fear in the laboratory in a controlled manner. Recently, this approach was used to test the anxiolytic potential of the atypical antipsychotic quetiapine in a randomized, placebo-controlled trial in a sample of $n = 58$ patients suffering from arachnophobia (Diemer et al., 2013). The laboratory

setting allowed the assessment of fear and anxiety in a multimodal manner, and to detect domain-specific drug effects.

One of the growing research areas in clinical psychology and psychiatry is the identification and investigation of endophenotypes. Endophenotypes are conceptualized as genetically determined traits that confer a risk of psychopathology. They are supposed to bridge the gap between genetics and diagnoses, representing underlying pathomechanisms that may be shared by various diagnoses. One such endophenotype is the fear-potentiated startle response, which has been linked to increased vulnerability for anxiety disorders. Startle paradigms can be easily combined with VR scenarios, allowing the assessment of endophenotypes in an ecologically valid environment (cf Glotzbach-Schoon et al., 2013). Many other applications of complex VR environments to investigate possible endophenotypes – which may be cognitive, psychological, or psychophysiological in nature – of different disorders are possible.

Future Perspectives in VR Therapy and Research

The last decades were associated with a continuous expansion of VR applications and research. Computer technology and software development are advancing at a fast pace, making a widespread use of VR technology in mental health areas likely. As for VRET, a particular increase of VR applications for the treatment of aviophobia and PTSD is expected, given the obvious advantages of using VR scenarios for these disorders. Particularly, augmented reality has the potential to further boost VR applications in research and health care.

In general, the development of VRET research in the last decade shows two trends: the expansion of the different applications, and the dissemination of VRET, i.e., the increase of its availability in the health care system. In terms of diagnoses, more research into VRET applications for the anxiety disorders, especially social phobia, PTSD, and panic disorder and agoraphobia is to be expected. Further, research into VR applications beyond anxiety is likely. In terms of availability, feasibility studies on the introduction of VRET into routine health care will be the next step and are bound to be conducted in this decade.

As for VR research, the possibilities provided by VR to investigate psychotherapeutic processes are only beginning to be used. Possible variables of interest during exposure-based treatments include changes in psychophysiological reactivity during exposure, homework assignments, and effects of additional treatment elements (e.g., attention focusing). The emerging applications of VR in basic research are numerous (see above). They are supplemented by technological possibilities that include the combination of VR scenarios with different assessment methods, among them physiological recordings, eye tracking, EEG, and neuroimaging techniques.

Virtue Ethics

Christine Swanton, University of Auckland, Auckland, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Virtue ethics is a type of normative ethical theory generally seen as opposed to both Kantian ethics and consequentialism. On orthodox conceptions, virtue ethics has been regarded as Aristotelian, but virtue ethics is now with greater frequency seen as belonging to a broader church including Confucian ethics, Hume, and even Nietzsche. Common to all virtue ethics is the centrality of character (understood in various ways) to ethics, although in applied ethics, the application of virtue concepts to action is a rich area of debate.

Virtue ethics is a type of normative ethical theory generally seen as opposed to both Kantian ethics and consequentialism. In its modern incarnations, it has been largely inspired by the eudaemonistic tradition of the ancient Greeks, and in particular Aristotle. However, we can expect further developments in virtue ethics that are inspired by other sources, such as Nietzsche and Hume. Virtue ethics is characterized by the centrality but not necessarily the primacy of character in normative ethical theory, where norms of excellence of character provide norms for both the good life in general and acting well and rightly. In virtue ethical traditions, norms of excellence of character are rich, and involve being well disposed in regard to reason, feelings, desires, motives, emotions, as well as action; hence the importance of the expression of fine inner states in virtue ethics. Problems for virtue ethics include the foundations of virtue, the universality of virtue, the relation between character and issues in applied ethics such as role obligations and right action generally, demands for codifiability and determinacy, and 'character skepticism' suggested by situationist psychology.

Definition

It has often been said that the development of virtue ethics (in modern dress) is in its infancy. For this reason, although virtue ethics is a type of substantive normative ethical theory opposed to consequentialism and Kantian ethics, its definition is contested (Swanton, 2013). The problem of definition is compounded by the fact that although much contemporary virtue ethics is neo-Aristotelian, it need not be, and has not always been. Increasingly, David Hume is being read in a way more sympathetic to virtue ethics, Nietzschean and neo-Confucian virtue ethics are developing, and Plato and Martineau have inspired 'agent-based' virtue ethics (Slote, 1996, 2001). Virtue ethicists, then, need not, and do not agree on such central questions as the definition of right action and what makes a trait of character a virtue. Common to virtue ethicists, however, is the view that virtue notions pertaining to character and action rather than duty, rules, or consequences is central to ethics. This is not to say that rules, consequences, and the motive of duty are not important, but virtue notions will produce virtue-centered conceptions of moral rightness, objectivity in ethics, impartiality, demandingness or stringency of ethics, and practice, which reconfigure the moral universe.

The major source of inspiration for the development of modern virtue ethics is Aristotle (1955), particularly his *Nicomachean Ethics*. Two central features of his view have influenced definitions of modern virtue ethics. The first is his idea that the judgment of a virtuous agent is the rule and the measure of the right. This feature has spawned the view that virtue ethics is opposed to moral rules and principles and that these must be entirely replaced by the judgment of a qualified judge (a virtuous agent). However, there are 'virtue rules' such as requirements to be kind, considerate, fair, courageous, and so on: rules that we use to educate our children into the moral life, and that we may use in morally charged situations where we might ask, for example, 'What would be the kind or tactful thing to do here?' Virtue ethicists, however, follow Anscombe (1958) in believing that moral rules should be couched in the 'thick' virtue concepts.

The second feature sometimes thought to be defining of virtue ethics is Aristotle's view that virtues are essentially connected with the flourishing of their possessor. David Hume, however, thought that there are four potential grounds for status as a virtue: agreeableness and usefulness to self and agreeableness and usefulness to others. What constitutes right action and what gives status as a virtue are points of disagreement among virtue ethicists, so particular conceptions of right action and virtue status should not be employed to define virtue ethics as such.

Content of Virtue Ethics

Discussion of the content of virtue ethics can center usefully on three issues: (1) virtue ethical conceptions of moral rightness of action, (2) the nature of virtue in virtue ethics, and (3) different conceptions of what makes a trait of character a virtue, within virtue ethics.

Virtue Ethical Conceptions of the Right

It is often thought that the virtue ethical conception of rightness, indeed one that is defining of virtue ethics is the following. (1) An act is right if and only if it is what a virtuous

agent would characteristically (i.e., acting in character) do in the circumstances (Hursthouse, 1996, 1999). However, other possibilities within virtue ethics exist, and have been canvassed. According to 'agent-based' virtue ethics, rightness is understood thus. (2) An act is right if and only if it exhibits good motivation (Slote, 1996, 2001). Statman (1997) alludes to another possibility. (3) An act is right if and only if it is expressive of virtuous character.

Finally, we might say (4) an act is right if and only if it hits the targets of relevant and contextually salient virtues in relation to action (Swanton, 2003, 2013). Concept (4) differs from (1) in that it is possible for a virtuous agent acting in character to do in the circumstances something that is wrong according to (4). For example, according to (4), an act expressive of a benevolent disposition, and benevolently motivated, may fail to be a benevolent act. For a virtuous agent is not omniscient, although she is (on orthodox views) endowed with practical wisdom and the act may turn out to be extremely harmful. For the same reason (4) differs from (2) and (3). Furthermore, virtuous acts, as opposed to actions from or expressive of a state of virtue, need not possess all the features required for action from a virtuous state (as Aristotle recognized). In certain contexts, they may not express fine character or even good motives. In short, a virtue ethicist may share the common conception of right action as one that is successful in hitting its target. Where virtue ethicists who share this view differ from, for example, consequentialists, is their conception of 'hitting the target.' The target is set not by consequentialist criteria of promoting the most good, but by the ends of the various virtues. These ends will of course differ from virtue to virtue, so unless one subscribes to a strong doctrine of the unity of the virtues, virtue ethicists will possess a pluralistic view of rightness of action.

Where virtue ethicists do not always require fine inner states for rightness (as opposed to goodness) of actions, they may distinguish between rightness and excellence of acts, where the criteria for the latter are more stringent than those for the former.

The Nature of Virtue in Virtue Ethics

A virtue is an excellence of character. It is a disposition of acknowledging or responding to items in the field of the virtue in an excellent way. According to virtue ethical conceptions of virtue, the standards of excellence point to states inside the agent, as well as to the world outside the agent. In short, for a virtue ethicist, the realization of the end of a virtue must express fine inner states, if that realization is to display virtue.

Virtues have a specialized focus, that is, they have a field. The field of a virtue may be human beings in general; one's children, property, friends, honors, and pleasure; the natural world, cultural and artistic objects, money, abstract objects such as knowledge, and states of affairs such as dangerous situations, interpersonal conflict; and so on. There are a wide variety of virtues that focus on different fields or domains – virtues such as friendship, courage, justice, environmental virtues, appropriate assertiveness, honesty, politeness and tact, liberality, generosity, as well as thrift. Some virtues are universal such as courage, temperance, and justice, while others are relative to roles, such as professional virtues and virtues of parenthood (call these role-differentiated virtues (Swanton, 2007a)). Yet others are relative to situation, for example, according to Aristotle, virtues whose field concerns (the expenditure of) money vary according to how much money one has, and range from thrift to 'magnificence.'

Insofar as 'virtue' is a success word, the form of acknowledgment of items in the field of a virtue required by a virtue must be appropriate or successful. What constitutes success or appropriateness will vary according to two types of things: first, according to the different kinds of morally significant feature in those items which it is the end of the virtue to recognize, sustain, further, or bring about (such as their value or status), and second, according to the differing forms or modes of moral acknowledgment of items required by the various virtues (such as promoting (value or good) or respecting individuals in ways befitting their status). Virtue ethicists will differ on what are the basic morally significant features in the items acknowledged and what are the basic forms of moral acknowledgment inherent in virtue. The former may include value, status, bonds, and good; the latter promotion, honoring (Pettit, 1997), respect, love, appreciation, and creativity. The important point is that the criteria of success in meeting the various ends of the different virtues will vary, depending on which forms of moral acknowledgment are involved in their exercise. We may ask, for example, whether such virtues as justice, benevolence, and friendship are centrally concerned with all, or some of, the following: the promotion of good, the promotion of value, the honoring of value, respect for individuals in ways befitting their status, or love for individuals in virtue of bonds between those individuals and the agent.

According to virtue ethicists, an exercise or manifestation of virtue requires the successful expression of fine inner states, that is, in displaying virtue, the agent must both have fine inner states and successfully express them in her behavior. For example, virtuous creativity does not merely involve meeting the standards for success in the external manifestation of creativity that confers artistic merit in the created product. The creative response must also be expressive of fine inner states, such as the expression of artistic passion, a desire to create something of value to society or of high artistic quality, practical wisdom in the production of value, originality, and a desire to create something novel, interesting, or original. Similarly, love as a virtuous response or form of moral acknowledgment is not merely the promotion of the good of an individual, or the inculcation of a belief in the beloved that she is loved. Virtuous love is expressive of genuinely caring motivation: motivation that is not pathological, such as passively or morbidly dependent. Again, respect for status as a virtuous response is not merely the formal trappings of respect according to societal convention.

Although virtue ethicists share the view that virtue requires excellence of inner states, what kinds of inner states need to be excellent for virtue to be displayed is a matter of some controversy. Neo-Aristotelians emphasize the necessity of practical wisdom, but this view has been challenged by work on the so-called virtues of ignorance (Driver, 1989), by those who emphasize the sufficiency of admirable motivation for virtue (Slote, 1996, 2001), and by those who emphasize the pivotal role of passion in the life of virtue (Solomon, 1998).

Say, for example, that benevolence as a virtue is concerned centrally with promoting the good of individuals, we still need to know answers to the following questions. Is it enough for benevolence to be displayed that the agents display good motives in their attempt to promote good? Is it necessary that she display practical wisdom? Is it sufficient that she display practical wisdom or is she also required to display knowledge in cases where there is large-scale ignorance concerning good? To what extent does virtue require rising above the general ignorance of a population or culture?

Some progress on the issue of what constitutes excellence in inner states appropriate to human beings may be secured if Nietzsche's emphasis on excellence in depth psychological states is followed up. For Nietzsche, virtuous action is action expressive of fine depth states, and this view enables him to draw a distinction between virtuous and nonvirtuous altruism, virtuous and nonvirtuous asceticism, and so on. Forms of beneficence, sublimation, and self-discipline, which are expressive of self-contempt and resentment, lack virtue for Nietzsche. Post-Nietzschean analytic-oriented psychologists also distinguish virtue and vice on the basis of depth states expressed in habitual behavior. For example, genuine and passive dependent or 'morbid' dependent love is distinguished on that basis by, for example, Horney (1951). Fromm (1977) too, distinguishes between healthy (benign) and unhealthy (malignant) forms of aggression. Rather than aggressiveness being simply characterized as a vice, Fromm's account distinguishes between malignant and benign forms based on the human's characterological orientation to the satisfaction of basic needs such as the needs for excitation or stimulation, and relatedness.

What Makes a Trait of Character a Virtue

On the issue of what makes a trait of character a virtue, virtue ethics can be divided into eudaemonistic and non-eudaemonistic forms.

Eudaemonism

According to eudaemonistic virtue ethics, which characterizes Greek and neo-Aristotelian virtue ethics in its modern form, virtue is at least partially constitutive of the flourishing of the possessor of the virtues. Common to all versions of eudaemonistic virtue ethics is the view that what constitutes the flourishing of the agent cannot be understood entirely independently from the idea of virtue itself. That is, in determining what the virtues are, we cannot simply ask, first, what is good for a person, and then define the virtues in terms of traits that promote that good. For example, according to Aristotle, fineness of character is the greatest good for a person. Pleasure without temperance, wealth without justice, and the possession of friends without the virtue of friendship is not good for an individual, that is, does not benefit an individual. However, unlike the Stoics, Aristotle did not believe that virtue is sufficient for eudaemonia or flourishing: a modicum of good fortune and money, and children who do not disgrace one, are also necessary.

Due to the fact that eudaemonistic virtue ethics has been the dominant form of virtue ethics, it has been the main target of opponents of virtue ethics. The most important and intractable criticisms involve the relation between being good for a human being and being good *qua* human being and the nature of the naturalism that ensues. Other criticisms include the following. Because eudaemonism does not understand flourishing to be characterizable wholly independently of virtue, it has been accused of circularity. However, a coherentist epistemology, which is indeed adopted by Aristotle and many neo-Aristotelians, may remove the sting from this criticism. It does so provided the network of concepts and background theories of human nature in which conceptions of virtue and flourishing are embedded is sufficiently rich, informed by the social sciences, broad ranging, and does not rely on a problematically narrow, prejudiced, and uninformed set of intuitions. Another criticism is the charge of egoism occasioned by the belief that, according to eudaemonism, the rationale for the virtues is their benefiting the possessor of the virtues. This criticism is met by the claim that virtuous action need not be, and is not standardly, motivated by the self-interest of the possessor of the virtue. This reply in turn begets the criticism of indirection, namely, the criticism that a paradoxical and unmotivated dissonance opens up between the rationale for status of a trait as a virtue and the motivation and rationale of virtuous action.

Noneudaemonistic Virtue Ethics

Criticisms such as these have motivated, at least in part, the development of noneudaemonistic virtue ethics, which does not require that status of a trait as a virtue is grounded in the flourishing of the possessor of the virtues. At least two non-eudaemonistic forms have been explored.

1. Agent-based virtue ethics. According to 'agent-based' views, developed by Slote and inspired by Plato and Martineau (1891), a virtue is a trait that is admirable, and its admirability need not be based on its contribution to further value, such as the welfare of human agents or the environment generally. Nor need a virtue be even partially constitutive of the flourishing of a human agent. Such a view relies for its development on aretaic intuitions about admirability, rather than the more standardly appealed to axiological intuitions about what is valuable.
2. Response views. Although all virtues are dispositions of appropriate responsiveness to or acknowledgment of items within their fields, according to response views this feature is what makes a trait of character a virtue. It is not also necessary that a virtue characteristically constitute (in part) the flourishing of the agent. Response views may be more or less pluralistic about both the bases of moral acknowledgment (such as bond, value, status, and the good for) and the forms of moral acknowledgment (such as promotion, honoring, love, respect, appreciation, and creativity). Response views that are genuinely virtue ethical insist that important goods and states (such as pleasure, money, and friends) cannot be understood as goods entirely independently of virtue (Swanton, 2003, 2013).

Intellectual Context of Modern Virtue Ethics

Three main concerns have motivated the rise of virtue ethics in recent times:

1. Increasing emphasis on the importance of good character and character education for a healthy society.
2. Dissatisfaction with rival moral theories – particularly consequentialism and Kantianism.
3. Increasing recognition of the centrality of virtue in philosophers such as Hume, Nietzsche, Confucius, and neo-Confucians.

The emphasis on character and the character training of children is increasingly thought to be important, indeed central, for an ethically sound society. Moral rules, where important, need to be made, interpreted, and applied in complex situations, and in ways that are not distorted by such vices as greed, impatience, cowardice, lack of perseverance, racism and other forms of hostility, callousness, oversensitivity, lack of concern for or overconcern with, fairness, and so on. A difficulty for a reorientation of ethical thought toward virtue ethics, in line with the above concern, is the apparent linkage of virtue ethics with social conservatism. This view, however, is based on several misunderstandings. First, virtue ethics as such is open as to how we delineate the virtues. Specific versions of virtue ethics will differ on this question. Second, although it would be agreed by all that it is imperative to bring up children to possess character traits that are not personally and socially destructive, virtue ethics as such is open as to whether a correct version of virtue ethics provides a monistic or pluralistic answer to the question 'What is a good life for a human being?' Third, it is sometimes thought that virtue ethics is too 'individualistic' and fails to appreciate the limitations of a virtuous agent, and her embeddedness in society. However, a virtue ethicist could agree that even a virtuous human agent necessarily has limited experience, possesses limited perspectives, and has limited expertise and knowledge. Accordingly, it is open to a virtue ethicist to adopt a dialogical view of virtues of practice, and moral epistemology generally (Swanton, 2003).

The philosophical/theoretic push to virtue ethics has been driven by several factors, including the following. One factor is dissatisfaction with the lack of emphasis on, or a denigration of, the 'inner' – feelings, emotions, passions, and practical wisdom – in the life of the moral agent. Virtue ethicists emphasize the importance of outer action as expressive of inner states: benevolence, for example, is not just a matter of promoting value or good. Fine emotions, for example, are important for the situational appreciation required by practical wisdom. Emphasis on the emotions also brings into view forms of moral acknowledgment not sufficiently emphasized in analytic philosophical ethics, such as (virtuous) caring and love. It also highlights the centrality in ethics of certain partialistic virtues such as parental love and friendship.

A second factor in the intellectual context of modern virtue ethics is its objection to decontextualized understandings of moral theory. For example, for a virtue ethicist, ethics is neither essentially impartial nor essentially partial. Rather there are both virtues and vices of impartiality, and virtues and vices of partiality relative to different fields. An understanding of partialistic vices, such as nepotism and favoritism (toward one of one's children, for example), and impartialistic vices (such as dispositions to seriously neglect near and dear in the interests of 'the common good'), requires a highly nuanced and contextualized understanding of the boundaries between these vices and allied virtues.

Related to the above feature of virtue ethics is a third and much-emphasized factor: skepticism about the codifiability of ethics in terms of decisive universal principles. Virtue ethicists favor a conception of ethical expertise that emphasizes experience and practical wisdom. Because of their emphasis on detail, particularity, and complexity, they recognize that moral expertise, which relies on knowledge of, for example, medicine, business, educational, and other practices, does not generalize to all contexts.

A fourth factor is a desire to make the concept of living well central to moral evaluation. Commonly for virtue ethicists, the supposed gap between the good life and the moral life is reduced via the desideratum of living a virtuous life. Living a virtuous life reduces this gap primarily through a reconfiguration of the contrast between altruism and self-interest. A virtuous agent, characteristically and in normal circumstances, enjoys the moral life as Aristotle points out, because her capacities for strength, love, concern, respect, and lack of resentment enable her to see her own concerns as not sharply in contrast with the interests of others. Increasing interest in understanding Nietzsche, Hume, and Confucius through virtue ethics has made this clear.

Virtue Ethics and Applied Ethics

The application of virtue ethics to social practice raises the question of an epistemology suitable for virtue ethics. Such an epistemology may be monological or dialogical. Commonly, it is thought that virtue ethics is inherently monological because the arbiter of rightness of action is thought to be the (or a) virtuous agent, that is, an agent of good moral character, practical wisdom, fine sensibilities, and the ability to appreciate a situation and context in fine detail. Nonvirtuous agents simply emulate virtuous ones. However, even virtuous agents are necessarily limited because of their human condition (e.g., a virtuous man cannot have the experiences of women who are contemplating an abortion). Arguably, a suitable virtue ethical epistemology for the world of practice, for example, education, medicine, business, aid work, family relations, must be properly socially grounded. Participants in a practice, recognizing their epistemic and other limitations, exercise the moral/epistemic virtues of practice, which include the dialogical virtues. These of course are legion, including imaginative deliberation, insight, perseverance, respect in various forms, open-mindedness, facilitativeness, and an absence of those vices that distort practical wisdom and communication, for example, cowardice, rigidity, hostility, callousness, excessive love of power, squeamishness, and lack of concern for or excessive concern for fairness. For a virtue ethicist, determining whether a participant is, for example, excessively concerned with fairness or insufficiently concerned with fairness is often a matter of fine judgment applied in contexts where many values are at stake, and knowledge and

appreciation of relevant facts, including the feelings, preferences, and so forth of affected parties, commonly is gleaned only through well-conducted dialogue.

Serious application of virtue ethics to ethics of roles in the analytic tradition is relatively speaking still in its infancy but see Oakley and Cocking (2001) and Swanton (2007b).

Skepticism about Character

One important criticism of virtue ethics derives from the social sciences, specifically 'situationist' psychology (Ross and Nisbett, 1991). According to some philosophers who make use of this psychology, virtue ethics is inadequate because it is based on a characterological psychology that is empirically inadequate. According to situationist psychology:

> Behavioral variation across a population owes more to situational differences than dispositional differences among persons. Individual dispositional differences are not as strongly behaviorally individuating as we might have supposed… (Doris, 1998: p. 507)

The claim that experiments such as Milgram's (1963) demonstrate the empirical inadequacy of virtue ethics because there is a lack of cross-situational consistency in behavior betrays a lack of understanding of the virtue ethicist's concept of virtue. For a virtue ethicist, a virtue is not simply a disposition to perform acts of a certain type (e.g., beneficent acts). The possession of virtue also requires the possession of fine inner states. Admittedly, Milgram's experiments show that a remarkable number of subjects administer electric shocks of considerable severity, in experimental situations of a certain type. The tendency to perform beneficent acts is arguably not as robust as one might hope. However, there was considerable variation in the mental states of those prepared to administer such shocks, and these differences may point to character traits of, for example, compassion, benevolence, respect for authority, and commitments, which manifest themselves in various ways in dilemmatic situations. According to Milgram, the subjects differed markedly in their emotional reactions to increasingly pressuring requests to administer shocks. Milgram claims that an unanticipated effect "was the extraordinary tension generated by the procedures." He says: "One might suppose that a subject would simply break off or continue as his conscience dictated. Yet this is far from what happened. There were striking reactions of tension and emotional strain." While some subjects reported and manifested intense strain and anguish, "some subjects (who had administered maximum shocks) had remained calm throughout the experiment, and displayed only minimal signs of tension from beginning to end" (Milgram, 1963: p. 376).

For the virtue ethicist, emotional reactions are crucial for the attribution of virtue and vice, and the mark of the virtuous is the propensity to violate a 'virtue rule' such as 'be benevolent' only with reluctance, anguish, and distress. The degree to which these emotions are present will vary according to the circumstances. Furthermore, it is clear from Milgram's account that the anguished saw themselves as operating under a rather severe virtue dilemma. A benevolent agent may also possess the virtues of respect for authority, trust, honoring commitments, and appreciation of (the value of) knowledge. All these virtues were in play during the experiment (1963). Subjects rightfully assessed the experimental situation as warranting trust, the honoring of a commitment, and as promoting a worthy objective. Now where virtues of, for example, trust and fidelity appeared in acute dilemmatic relation to another – nonmaleficence – most subjects arguably gave insufficient weight to the latter. But virtue ethicists are not committed to the view that many actual agents are capable of resolving such dilemmas correctly when under severe stress. The degree of virtue in agents is, however, able to be determined by their emotional reactions to their admittedly faulty resolutions of dilemma (e.g., reactions of anguish or indifference). And those differences were evident. It is open to the virtue ethicist to argue that while trust was not misplaced, and although obedience to authority is a virtue, in this case most subjects displayed this virtue to excess. Arguably, this failure hindered the exercise of the virtue of nonmaleficence present in those who suffered anguish.

An excellent book-length reply to the situationist critique is Snow (2010). In general, according to virtue ethicists, good character is a centrally important component of the good life for an individual in society, and virtue ethics is a philosophically rich and fruitful approach to moral theory. The further development of this theory requires cooperation with the social sciences, if a richer understanding of virtue, as an excellence of character in human beings, is to be obtained.

Vision, High-Level Theory of

Johan Wagemans, University of Leuven (KU Leuven), Leuven, Belgium

Abstract

In a hierarchical view on vision, low-level vision concerns the extraction of simple, local features from retinal images, while high-level vision concerns the interpretation of their meaning. Classic work on object recognition is reviewed, followed by more recent work on scene interpretation, action and event understanding, and appreciation of visual art. In these areas, the evidence supports an intricate interplay between low-, mid, and high-level visions, which blurs the traditional distinctions. Alternative frameworks, such as reverse hierarchy theory and hierarchical predictive coding, are proposed to explain better what is currently known about high-level vision.

Introduction

The concept of 'high-level vision' is used to denote aspects of vision that are influenced by information stored in memory such as an object's identity, its name, or the context in which it belongs. It is usually distinguished from low-level visual processing, which is primarily driven by the visual input. High-level vision involves functions such as object recognition, face perception, picture naming, visual categorization, scene interpretation, action and event understanding, and even appreciation of visual art.

Background

In hierarchical models of vision (e.g., Marr, 1982; Serre et al., 2007), higher levels of visual processing operate on the building blocks delivered by more primitive visual mechanisms. In Marr's approach to perception, each stage has its own algorithms and its own format of representing processing output. The primal sketch represents the basic features and their spatial relations (low-level vision) and the 2.5-dimensional (2.5-D) sketch represents surfaces and shapes from the observer's viewpoint (midlevel vision). Recognition consists of establishing a match between the descriptions derived from the visual input and those stored in visual long-term memory. Marr was convinced that this required a representation of the full three-dimensional (3-D) structure of an object and its components in a so-called 3-D object model (high-level vision).

Marr's approach is more than 30 years old now, but it is still highly influential as a framework to understanding vision in terms of representations and computations. However, his assumption of strictly bottom–up processing in sequential stages has gradually lost attraction. One reason for this theoretical evolution has been the increased popularity of models in which different levels of processing interact with each other. Partial outputs from lower level processes initiate higher level processes and the outputs of higher level processes feed back into the lower level processes. When different levels are distinguished in more recent theories, great care is taken to avoid the assumption of strict sequential processing.

However, the issue of where early vision ends, where high-level vision starts, and how to demarcate the two has remained important. Pylyshyn (1999) has proposed the notion of cognitive impenetrability as the major criterion for separating early (or low-level) vision from later (or higher level) vision. Early visual processes run autonomously – they cannot be influenced by what is known about the world or expected in a specific situation. Most aspects of visual processing that seem cognitive (e.g., recovering unique 3-D percepts from ambiguous two-dimensional inputs) are attributed to embodied natural constraints derived from principles of optics and projective geometry, internal to the visual mechanisms themselves. Only effects of object-specific beliefs on earlier visual processing would count as cognitive penetration. A large number of so-called top–down effects of higher level processes on early vision are then explained as effects of attention (preceding early vision) or as postperceptual effects on the decision stage based on the perceptual output.

Implicit in Pylyshyn's (1999) effort to delineate early vision from cognitive influences is his belief – shared by many vision scientists – that real scientific progress is possible only in early vision. Arguably, however, in the last decades considerable progress has been made in the area of high-level vision as well, initially with regard to object recognition, but more recently also with regard to the interpretation of scenes, actions, events, and even art.

Classic Work on Object Recognition

Biederman (1987)

Object recognition concerns the identification of an object as a specific entity (i.e., semantic recognition) or the ability to tell that one has seen the object before (i.e., episodic recognition). Building on Marr's ideas about matching perceptually derived 3-D volumetric descriptions to those stored in memory, Biederman (1987) has formulated a theory of object recognition that has incorporated some crucial aspects of midlevel vision as well.

Biederman proposed that objects are identified at their entry level on the basis of a structural description of its components and their spatial relations. All object parts are modeled by a limited number of simple primitives called 'geons,' a specific

subset of generalized cones. A generalized cone is the volume swept out by a cross section moving along an axis. Geons are defined by the categorical attributes on the following dimensions: the axis (straight or curved), the shape of the cross section (straight or curved, symmetric or asymmetric), and the size of the cross section (constant, expanded, or expanded and contracted).

One major claim in Biederman's recognition-by-components (RBC) theory is that geons themselves are viewpoint invariant because the underlying dimensions can be distinguished on the basis of so-called nonaccidental properties (NAPs). These are special features in the image, such as collinearity, curvilinearity, cotermination, parallelism, and symmetry, which are reliable in the sense that they are most likely caused by similar characteristics in 3-D space, at least under the assumption of a general viewpoint. Biederman argued that Gestalt principles of grouping support the extraction of these NAPs and that they are thus detected fast and reliably enough to support bottom–up identification of geons.

Allowing for different combinations of different geons, with different spatial relations between them, yields enormous combinatorial possibilities. Based on computational grounds, Biederman argued that the recovery of a small number of geons (3 or 4) is enough to quickly recognize complex objects even when they are occluded, rotated in depth, degraded, or lacking color or texture. This claim has also been supported empirically by experiments in which parts of objects (in fact, line drawings of objects) were deleted until only two or three parts were left. Other supporting evidence came from recognition of contour-deleted line drawings (which is possible as long as the geons are recoverable), priming with contour-deleted pictures (which is situated at the level of the parts, not the image fragments and not the whole picture), and viewpoint invariance of 3-D object recognition (under certain limited conditions). In more recent years, additional support for this theory of object recognition was obtained in infants, non-Western cultures, and at neural levels.

Edelman (1999)

Another important theoretical step forward in high-level vision was Edelman's (1999) book on *Representation and Recognition in Vision*. Edelman argued that the attempt to base recognition on geometrically reconstructed representations of distal objects (like Marr's 2.5-D sketch) suffers from serious theoretical and practical problems. First, it would lead to the homunculus problem and, more pragmatically, it appears, at least up till now, not to work, not even when using the most sophisticated computer vision techniques. The major reason for this failure might be that previous approaches have tried to achieve veridicality of object representation by aiming for isomorphisms between objects in the world and their corresponding internal representations (i.e., first-order isomorphism or representation by similarity). Instead, Edelman proposed to aim for the formally just as good isomorphism between the relations among several external objects and the relations among their corresponding internal representations (i.e., second-order isomorphism or representation of similarity).

To this end, Edelman introduced the notion of a shape space, a formalism borrowed from mathematical statistics. A shape space is a metric space in which each point corresponds to a particular shape and in which geometric similarity between shapes can be defined rigorously as proximity, a quantity inversely related to distance. A novel shape (or a novel view of a previously seen shape) can be localized in such a shape space based on its similarity to known objects (or stored views of known objects). A tuned unit (or module of units) that responds optimally to some shape (i.e., the landmark) and progressively less to progressively less similar shapes, is enough to implement this mechanism. Edelman used a radial basis function approximation network that can be trained and then generalizes its response from a series of given views of an object to other views of that object. As a by-product of this learning, the network also responds progressively less to progressively less similar objects, precisely what is needed for it to work as an active landmark in internal shape space. This scheme works not only for known objects but also for novel objects. The trick is that a new object must be represented by a vector of proximities to several reference shapes or landmarks. For example, even if one has never seen a giraffe before, it is possible to compute the proximities to known animals such as a camel, a goat, a pig, or even a leopard.

Edelman has called this system a 'chorus of prototypes' to emphasize that the prototypical landmarks act together in representing shape. Initial simulation results with this system have been encouraging, especially in light of the wide variety of tasks: identification of novel views of familiar objects, categorization of novel object views, discrimination among views of novel objects, local viewpoint invariance for novel objects, recovery of a standard view and of pose for novel objects, prediction of a novel view for a novel object, and so on. None of its theoretical competitors (e.g., Biederman's RBC) could handle such a variety of tasks.

More Recent Work on Scene Interpretation, Action and Event Understanding, and Art Appreciation

While object recognition was at the center of high-level vision in the 1980s and 1990s, the last couple of decades have seen a significant surge of interest in other aspects of high-level vision, which appear even harder because of the complexity of the stimuli to be interpreted and the variety of possible responses (interpretations and even social and emotional reactions).

Scene Interpretation

Scene interpretation has always constituted a great challenge, because scenes are more complex than isolated objects; they consist of several different objects in several mutual spatial relationships, usually with more clutter and stronger effects of lighting and occlusion than single objects. In a fruitful collaboration between psychology and computer vision, Oliva and Torralba (2006) showed that it is possible to extract a number of interesting scene characteristics from relatively simple image features. They analyzed global image characteristics instead of first segmenting the image into regions, extracting isolated object shapes, and computing spatial relations between them. For instance, the roughness of

the luminance profile across the whole image happens to be smooth for open natural scenes like a beach and rough for closed urban scenes, the spatial envelope can be low or high on openness and expansion, and so on.

When lots of images of different scenes are plotted in a multidimensional graph of such global image characteristics, they appear to cluster together by semantic category (e.g., street images versus highway images), which means that the gist of a scene can be recognized on the basis of a combination of global image characteristics. In total, seven global scene properties could be identified that can easily be derived from natural images and that appear important for scene interpretation: openness, expansion, mean depth, temperature, transience, concealment, and navigation. Greene and Oliva (2009) then showed experimentally that human perceivers are also capable of extracting these global scene properties from natural images flashed as briefly as 20–70 ms. Similar critical exposure durations were also obtained for scene categorization of the images (e.g., desert, forest, mountain, and ocean). The theoretically important message from this line of work is that semantically high-level interpretation is sometimes relatively easy for the visual system to derive from surprisingly simple low-level (but global) image features.

Action and Event Understanding

Humans have a strong tendency to interpret sequences of movements as meaningful events and actions, even with simple geometric shapes moving dynamically across a screen. Building on early work by Albert Michotte and Fritz Heider, Brian Scholl and colleagues have recently studied such action and event understanding in more detail. Specifically, they wanted to show that the perception of animacy is really a perceptual phenomenon and not the result of a higher order cognitive judgment. In order to do this, they systematically manipulated a number of subtle stimulus parameters and measured their effect on task performance, in addition to their effect on the perceptual impressions as such.

In one series of experiments (Gao et al., 2009), simple geometric shapes moving dynamically across a screen were interpreted as the chasing of one shape (a 'sheep') by another shape (a 'wolf'), amidst a large number of other shapes. Observers could control the sheep's movements by moving the computer mouse and were instructed to avoid being touched ('caught') by the wolf. While the sheep was highlighted by being drawn in a different color, the wolf looked identical to the distracters and could therefore be identified only on the basis of its spatiotemporal behavior (i.e., whether it followed the sheep's movement or not). Performance in this chasing detection task was strongly dependent on the chasing subtlety, which was manipulated by the maximal angular deviation of the wolf's heading direction relative to perfectly following the sheep (for a demonstration, see http://www.yale.edu/perception/chasing/). When the chasing subtlety was minimal, the chasing was obvious and could easily be avoided. When the chasing subtlety was maximal, performance was high again but mainly because the wolf was actually not chasing competently. For a large range of intermediate levels of chasing subtlety, the wolf was chasing competently but the chasing was difficult to detect. Such a nice dissociation between actual chasing and perceived chasing as a function of a subtle stimulus manipulation supports the idea that perceived animacy is really a perceptual process (with nicely controllable psychophysical characteristics) and not the consequence of a higher level cognitive judgment. Indeed, subjects were often unaware of the differences between the different stimulus conditions, which had a clear effect on their task performance.

In another series of experiments (Gao et al., 2010), a green disc moved quasirandomly across the screen, along with a number of 'dart' shapes that moved completely independently from one another and from the green disc. In one condition, the darts' orientations were continuously adjusted during their motion trajectories so that they were always pointing directly at the disc. Observers spontaneously misinterpreted this in terms of animate behavior such as chasing, presumably on the basis of the darts' facing their target, a phenomenon that the authors have called the 'wolfpack effect' (for a demonstration, see http://www.yale.edu/perception/wolfpack/). In a perpendicular control condition, the facing direction was updated continuously to be pointing 90° away from the green disc, which completely eliminated the wolfpack effect. Hence, although these two conditions were well-matched in terms of all lower level properties, one evoked a rich percept of animacy and intentionality, while the other did not.

In one of the experiments with these stimuli, the authors combined this manipulation with the explicit task of detecting a wolf, this time clearly distinguished from both the sheep and the darts by being colored differently. When the wolfpack was facing the sheep, performance was reduced by more than 20%, compared to the perpendicular control condition, as if the wolfpack (which consisted of independently moving darts) distracted attention away from the real wolf (moving in relation to the sheep). When the wolfpack was facing the wolf, the effect was attenuated. Hence, although subjects were fully informed about the irrelevance of the darts' orientations, they could not refrain from interpreting them as an animate and intentional wolfpack. This provides strong evidence that this is an automatic perceptual process rather than a higher level cognitive judgment.

Art Appreciation

Art is still more complex, obviously, and one's reactions are even richer, from pure perceptual stimulation to aesthetic pleasure and the experience of thrills and being deeply moved. In fact, trying to understand people's reactions to art requires the integration of all the processes psychology usually distinguishes (attention, perception, emotion, etc.) and of all the factors known to influence these processes (in addition to stimulus factors, also the person's background, interest, knowledge, expertise, etc.). In this way, experimental psychoaesthetics – the science of understanding art appreciation – is a fascinating microcosmos and test bed for psychology as a whole (Wagemans, 2011). In spite of these complexities, here as well recent research has made good progress in relating these very high-level processes to known midlevel visual processes.

A good example is a study by Koenderink et al. (2012) with line drawings of human figures made by Picasso in the 1940s. These drawings provide an interesting case study of high-level vision because they contain a lot of white space, which appears to be filled in one's mind when interpreting them as bodily surfaces in particular attitudes (i.e., orientations in space) and because Picasso intentionally combined multiple perspectives in a single drawing, which means that one can never have experienced such an image before. As a rendering of a 3-D object, the line drawing is blatantly incorrect and yet one has no problem in seeing a human figure with clearly defined body parts that are visually coherent and meaningful.

Koenderink et al. asked their observers to adjust an elliptical gauge figure (which looks a bit like a pushpin with its needle sticking out) so as to appear as a circle painted on the surface, at a large number of predetermined locations within the surface area bounded by a simple outline consisting of a few well-placed pen strokes. Based on these local measurements, a reconstruction of the global shape is possible, which can then be analyzed in great detail, for instance, to compare the perceived shape between different observers, to relate the perceived shape to local image cues, and so on. In the context of this article, only a few highlights can be summarized. First, the purely planar structure of the drawings is sufficient to account for much, although by no means all of the data. The observed reliefs of the body surfaces have structures that are twisted in depth such that their outlines are nonplanar. When looking at these images, the perceptual processes giving rise to awareness apparently act in depth (e.g., they may make an arm move forward or backward in pictorial space). Depth cues such as contour curvature, contour terminations, and T-junctions (which also play an important role in Biederman's RBC theory) have a noticeable influence on the observed reliefs, but they are insufficient to account for all of the structure in the data. In these Picasso drawings, most of the paper is left blank and perceived structure must therefore be due to effects from the neighborhood of that area or it has to be supplied by the perceiver. Examples of both were obtained in this study. A clear instance of the former case is a convexly curved arc whose direction changes continuously over 60° or more, perceived as an ovoid shape (e.g., breasts or buttocks). A clear instance of the latter case involves the relief of the human back, which was perceived as singly convex by one observer and including a centrally elongated groove of the spine by another observer. These observers clearly applied a different type of template of the human back to fill in the empty space in the drawing.

It is tempting to speculate that the interplay between these image-based and knowledge-based influences, and the inter-individual variations in this interplay, may well contribute to the aesthetic pleasure experienced by the perceiver and to the artistic value of the artwork. Perhaps such a piece of visual art, which provides just enough cues to induce particular percepts, while still leaving enough to the perceiver's imagination, is appreciated so much because it imposes the optimal degree of constraints on our perceptual awareness (Van de Cruys and Wagemans, 2011). Such a view on the rewarding aspects of art is compatible with one of the new theoretical frameworks replacing the traditional view on the hierarchy of low-, mid-, and high-level visions.

New Theoretical Frameworks Replacing the Traditional Hierarchical View

The current mainstream view of human visual cortex emphasizes functional specialization and hierarchical organization (e.g., Grill-Spector and Malach, 2004). Functional specialization means that different parts of the brain are assumed to carry out different functions, for simple stimulus attributes like form, motion, and color, as well as for more complex semantic categories such as faces, bodies, and places (e.g., Kanwisher, 2010). This also involves the distinction between ventral stream processing for visual awareness of object identity and dorsal stream processing for visually guided action, also labeled as 'what' versus 'where' stream processing (e.g., Goodale and Milner, 1992). The hierarchical organization entails a number of anatomical and functional characteristics of the different cortical areas along the ventral stream (e.g., V1, V2, V3a, V4, LOC), such as increasing receptive field size, decreasing retinotopy, increasing invariance, and increasing complexity of the features that are encoded, from simple stimulus features like orientation and spatial frequency, to junctions, parts, and whole objects (e.g., Serre et al., 2007).

In line with this anatomical and functional characterization of human visual cortex, the current mainstream view of visual processing (often implicitly) assumes that high-level percepts are constructed from combinations of low-level attributes, much like whole objects are assembled from parts (cf. Biederman's RBC), parts arising from spatial relationships between line segments and junctions, line segments being the outputs from edge detectors, and so on. In such a view, processing is mainly feedforward, starting from local features encoded in low-level areas and ending with global interpretations in high-level areas. In the section 'More Recent Work on Scene Interpretation, Action and Event Understanding, and Art Appreciation,' several lines of research have been reviewed, showing that such a simple story needs revision. Scenes can be interpreted quickly based on global but low-level image characteristics. Dynamic displays can give rise to automatic, spontaneous high-level interpretations of animacy and intentions, which appear strictly tied to simple perceptual attributes like relative orientations and trajectories. High-level percepts of human bodies from simple line drawings consist of a mixture of low-level and midlevel processing of image features as well as knowledge-based shape templates, and aesthetic pleasure may be derived from the mixture of image-based constraints and subjective filling in of empty spaces in 'the eye of the beholder.' In the last decade, a number of alternative views on the relationships between the levels of cortical processing have emerged that might do better justice to these findings.

Reverse Hierarchy Theory

First, Hochstein and Ahissar (2002) have proposed the 'reverse hierarchy theory,' in which they argue that a fast feedforward sweep quickly activates global percepts (e.g., the overall gist of a scene) in high-level areas with large receptive fields, whereas feedback from these higher areas to lower areas and recurrent processing in the low-level areas with small receptive fields is necessary for fine-grained processing of local details (e.g., a difficult visual search task). Hence, this theory

distinguishes the anatomical and structural aspects of the hierarchy of the visual system (low- versus high-level representations) from the temporal and functional aspects of it (early versus late stages of processing). Reverse hierarchy theory can explain a lot of the findings on fast object and scene categorization, visual search, perceptual learning, and so on.

Second, Moshe Bar and colleagues (e.g., Bar, 2003; Bar et al., 2006) have proposed a general theory of visual object recognition, in which two streams of processing initially occur in parallel, one in which the high spatial frequencies of input images are processed in a relatively slow, feedforward sequence according to the standard hierarchy of stages (V1, V2, V4, …), and another in which the low spatial frequencies are quickly transmitted to areas in the prefrontal cortex to generate hypotheses about possible identities of the object as well as their most likely scene context, after which these two streams are integrated and refined in an iterative, reentrant way. Again, this view can explain a lot of the findings on object recognition, scene context effects, priming, and so on.

Both these views are similar in spirit to traditional ideas from Gestalt psychology (for recent reviews, see Wagemans et al., 2012a,b), because they both postulate that global processing comes first, both are highly interactive and dynamic views on cortical processing, and they are not even limited to purely visual areas. Indeed, Moshe Bar has more recently extended his view to include cognitive interpretation and emotional significance (e.g., Bar, 2007; Barrett and Bar, 2009), which would make it more suitable to explain the findings on animacy, intentionality, and aesthetic pleasure reviewed above. This view also bears family resemblance to another recent theoretical framework, called 'hierarchical predictive coding.'

Hierarchical Predictive Coding

In the mainstream view summarized before, the brain was largely conceived to passively encode and decode the available sensory information. In this new framework of understanding cortical processing, the brain is instead conceived to actively predict the forthcoming input. According to this so-called predictive coding account (for reviews, see Clark, 2013; Huang and Rao, 2011), expectations about the state of the world are stored or generated in higher level brain areas, which are then sent to lower level areas, where they are evaluated against the upcoming information. Discrepancies between prior expectations and the actual input are translated into prediction error (or 'surprise') signals, which are sent to higher level areas, where they are used to update the predictions. This process is reiterated across the complete cortical hierarchy until the prediction error is sufficiently minimized at all levels, which is why this view is labeled as 'hierarchical predictive coding.'

Friston (2010) has argued that this view of the brain as a hierarchical network, in which predictions are generated and evaluated, has the potential of unifying perception, action, and learning into a single theoretical framework. There is currently a blossoming literature in which many psychophysical and neural findings are reconceptualized in a predictive coding framework. In addition, new studies are carried out to try to support this view with direct empirical evidence, mainly as enhanced neural responses to violations of expected input. These findings are then taken to confirm the idea that higher level expectations are used to 'explain away' the lower level representations that are compatible with these expectations (Clark, 2013). It remains to be seen how productive this new framework will be in making unique, falsifiable predictions that cannot be made by other theories, and that are then also supported empirically.

Abstract

Models of visual function may be construed as low level theories in two related senses. First, theories may be regarded as low level when they deal explicitly with the lower levels of the retino-cortical visual hierarchy. For the purposes of this article this will be assumed to comprise the retina and cortical areas from primary visual cortex through area V4 in the ventral or form vision pathway. The second sense in which models may be construed as low level is with regard to the level of description. Thus, while high level vision models generally deal with abstractions that are at present but tenuously related to underlying neural network activity, low level vision theories are concerned with the explicit development of neural network models which are consistent with single unit neurophysiology on the one hand and are capable of predicting perceptual data on the other. The models discussed in this article are all low level in this network sense as well. Thus, this article will focus on contemporary neural models of retinal, striate, and extrastriate cortical processing in the form vision system. Key topics include 'feedback,' 'gain controls,' 'configural pooling,' and 'cooperative–competitive interactions.'

Introduction

The primate visual system comprises over 30 cortical areas in addition to the retina and other subcortical structures. To model the lower levels of form vision or motion perception, it therefore becomes necessary to develop neural network theories of retinal, striate, and extrastriate cortical function that are consistent with known anatomy and physiology and that are capable of predicting relevant psychophysical data. The mathematical techniques necessary for this enterprise include convolution and 'nonlinear dynamical systems' theory (see also Self-Organizing Dynamical Systems). This article will review current theories of retinal and striate cortical function followed by a discussion of neural models related to areas 'V2' and 'V4' in the form vision hierarchy.

Theories of Retinal Function

Retinal neurons transform the optical image in order to extract biologically relevant visual information concerning light intensity changes in space (i.e., contours and edges), changes in time, and chromaticity. Furthermore, the retina must shift its operating point so as to signal useful information over more than a brightness range, a process termed light adaptation. These transformations are carried out by networks comprising at least five different types of neurons: photoreceptors, bipolar cells, horizontal cells, ama-crine cells, and ganglion cells (see Wässle and Boycott, 1991). As the extraction of color information is covered elsewhere let us focus here on light adaptation and the extraction of contours.

Light intensities in natural scenes cover more than a 10^6 range, yet the ganglion cells providing the retinal output to the brain can only respond over about a 300:1 range. Thus, the retina must compute the mean level of illumination at any given time and adjust the circuitry to respond to about a 300:1 range around that operating point. Key experiments on retinal light adaptation have demonstrated that there are two major processes involved: one subtractive and one divisive (see Hood, 1998). The direct path through the retina involves photoreceptors activating bipolar cells, which in turn activate ganglion cells. In addition the retina incorporates two major feedback loops: (a) from photoreceptors to horizontal cells then back to photoreceptors and (b) from bipolars to amacrine cells back to bipolars. A recent retinal model has tentatively identified each of these loops with one of the light adaptation processes (Wilson, 1997). In particular, loop (a) was conjectured to provide sub-tractive feedback, while loop (b) was suggested to be the site of divisive feedback. In a subtractive loop, the feedback signal is subtracted from the loop input, while in a divisive loop, the feedback signal divides the loop input signal thus reducing its gain. (More likely, each feedback loop incorporates both subtraction and division, suggesting a somewhat more complex formulation.) It is significant that both horizontal cells and the amacrine cells, the key units in these two feedback loops, have a relatively broad horizontal spread across the retinal surface and thus provide feedback that is averaged over an extended area. Subtractive feedback is well understood in the context of linear systems theory, but divisive feedback moves into the realm of 'nonlinear dynamics'. Designating the bipolar cell response as B, the amacrine feedback response as A, and the light-derived signal received from the photoreceptors as L, the simplest divisive feedback equations are of the form (Wilson, 1997):

$$\begin{aligned} \frac{dB}{dt} &= -B + \frac{L}{1+A} \\ \frac{dA}{dt} &= -A + B^N \end{aligned} \qquad [1]$$

These equations may be analyzed using standard techniques (Wilson, 1999) of nonlinear dynamical systems theory. In particular, one can solve for the steady state or equilibrium value at which $dB/dt = 0$ and $dA/dt = 0$. The results for very small and very large values of L are approximately:

$$\begin{aligned} B &\approx L \text{ for } L \leq 1 \\ B &\approx L^{1/(N+1)} \text{ for } L \gg 1 \end{aligned} \qquad [2]$$

Thus, at very low light intensity levels the bipolar response B is approximately equal to its input, so there is no attenuation of weak signals. At high light intensity levels, however, B is compressed to approximately the $(N+1)$ root of L. For $N = 2$, a physiologically plausible figure, the divisive feedback loop in eqn [1] will compress an $L = 10^6$ input into a $B = 100$ output, easily compatible with the response range of the ganglion cells. A further property of eqn [1] is that the temporal response becomes more transient as L increases (Wilson, 1999), and this change is well documented in the literature on flicker sensitivity and light adaptation (Wilson, 1997).

As is well known, retinal receptive fields have an excitatory center and inhibitory surround (or vice versa) spatial profile (see also Visual Perception, Neural Basis of). Direct bipolar input to the ganglion cells produces the receptive field center, while the lateral spread of both horizontal and amacrine cells creates the antagonistic surround. Thus, the neurons engaged in light adaptation via feedback also produce the spatial surround of ganglion cell receptive fields. As is evident from the discussion above, divisive feedback has almost no effect at low light levels (eqn [2]), so one would expect receptive field surrounds to be very weak at low luminances but much stronger at higher luminances, and this has been demonstrated experimentally. For some simulation purposes the spatial characteristics of retinal receptive fields may be approximated as a circularly symmetric difference of Gaussians:

$$G(R) = A\exp\left(-R^2/\sigma_c^2\right) - B(L)\exp\left(-R^2/\sigma_s^2\right) \qquad [3]$$

where R is radius, and σ_c and σ_s are the space constants of the center and surround, respectively. The inhibitory gain $B(L)$ would vary from $B(0) \approx 0$ to $B(L) \approx A\,\sigma_c/\sigma_s$ for $L \gg 0$, which makes the integral of the receptive field $\int G\,dR = 0$. For further discussion of retinal models see Wilson (1997) and Hood (1998).

Theories of Striate Cortical Function

Hubel and Wiesel (1968) categorized striate (V1) cortical cells as simple or complex (see also Visual Perception, Neural Basis of). Both of these cell types show a preference for a particular orientation and also for a range of spatial frequencies. The now classical model for a simple cell receptive field (RF) is just an oriented linear filter with parallel excitatory and inhibitory zones defined by horizontal (x) and vertical (y) coordinates:

$$\begin{aligned} RF(x,y) &= A\left\{\exp\left(-x^2/\sigma_c^2\right) - \frac{\sigma_c}{\sigma_s}\exp\left(-x^2/\sigma_s^2\right)\right\} \\ &\times \exp\left(-y^2/\sigma_y^2\right) \end{aligned} \qquad [4]$$

Equation [4] describes a vertically oriented receptive field, but other orientations (varying in about 15° increments between 0° and 180°) can be produced by coordinate rotation. Based on physiological data, $\sigma_y \approx 3.2\sigma_c$ produces appropriate orientation band-widths. The activation $R(x, y)$ of a cortical array of simple cell receptive fields is produced by convolution:

$$R(x,y) = \iint_{-\infty}^{\infty} RF(x-x', y-y')I(x', y')\mathrm{d}x'\mathrm{d}y' \qquad [5]$$

where $I(x', y')$ represents the distribution of light in the image. Simulated neural responses are then produced by passing the results of eqn [5] through a nonlinear function exhibiting both a threshold and saturation such as the Naka–Rushton function

$$S(R) = \left\{\begin{array}{ll} \frac{MR^N}{\beta^N+R^N} & \text{for } R \geq 0 \\ 0 & \text{for } R < 0 \end{array}\right\} \qquad [6]$$

where M is the maximum response level and N ≈ 2–3 for cortical neurons. As $S(R) = M/2$ when $R = \beta$, β is referred to as the semisaturation constant. Dynamics may now be added to this formulation as follows (Wilson, 1999):

$$\tau\frac{\mathrm{d}E}{\mathrm{d}t} = -E + S(R) \qquad [7]$$

where E is the excitatory firing rate and τ is the time constant for the rate of exponential approach to the asymptotic firing rate.

The simple cell model in eqns [4–7] can be used to generate complex networks of interconnected model neurons for simulations of cortical function (Wilson, 1999). However, contemporary research indicates that orientation selectivity is more complex than this. In particular, the linear filtering in eqn [4] suggests that orientation tuning originates entirely from a linear superposition of nonoriented lateral geniculate (LGN) filters similar to that in eqn [3]. While this was Hubel and Wiesel's (1968) original suggestion for orientation selectivity, the preponderance of evidence now supports additional factors in orientation tuning. First, convergence of as few as two nonoriented LGN filters conveys a modest orientation bias on cortical neurons. This very broad orientation bias is then sharpened considerably by two operations occurring in neural networks at the cortical level: contrast gain control and collinear facilitation (Sompolinski and Shapley, 1997).

Contrast gain controls were first modeled by Heeger (1991) as divisive feedback operations. He suggested that the summed activity of many different oriented units provided a divisive feedback signal to each of the units in turn. The divisive feedback loop in eqn [1] can be altered to function as a cortical gain control as follows:

$$\begin{aligned} \tau\frac{\mathrm{d}E_\theta}{\mathrm{d}t} &= -E_\theta + S\left[\frac{R_\theta}{1+A}\right] = \frac{MR_\theta^N}{\beta_\theta^N(1+A)^N + R_\theta^N} \\ \frac{\mathrm{d}A}{\mathrm{d}t} &= -A + \sum_\theta E_\theta \end{aligned} \qquad [8]$$

where θ designates the preferred orientation of each unit. Substitution of the Naka–Rushton function S from eqn [6] and rearrangement shows that this cortical divisive feedback circuit has the effect of scaling β by $(1+A)$. This network has been implemented and shown to sharpen cortical orientation tuning (Wilson, 1993). Due to the dynamics of the network, this orientation sharpening evolves over time as the divisive feedback takes effect, and this has recently been shown to occur in most cortical neurons (Sompolinsky and Shapley, 1997).

The final contribution to cortical orientation selectivity is provided by collinear facilitation (Sompolinsky and Shapley, 1997). Recent evidence indicates that neurons with the same preferred orientation are interconnected if their receptive fields are situated on a common line defined by their preferred orientation. Such reciprocally linked receptive fields are typically separated by 1–2 receptive field lengths so that their

mutual facilitation will only be triggered by stimulus edges of sufficient length. The excitatory connections are probably mediated by NMDA receptors so that both cells in a collinear pair must be independently activated by the stimulus for facilitation to occur. Obviously, collinear facilitation will sharpen orientation tuning when measured with extended lines or gratings. The function of collinear facilitation is to enhance the salience of extended contours, thus making them prominent candidates for further processing.

Global Processes in Extrastriate Form Vision

The complex cells of Hubel and Wiesel can be readily modeled by spatial pooling of simple cells with the same preferred orientation. More interesting are end-stopped complex cells, which are sensitive to both contour length and curvature. As illustrated in Figure 1(a), an end-stopped complex cell can be modeled by full-wave rectification of simple cell responses followed by second-stage pooling using a 2–3 times larger version of the oriented filter defined by eqn [4]. Full-wave rectification is mathematically equivalent to summing responses from both on-center and off-center simple cells that have the same spatial location and preferred orientation. The first-and second-stage filters in this filter–rectify–filter sequence usually have different preferred orientations, with the orthogonal case being illustrated in Figure 1(a). The optimal line stimulus for this end-stopped unit will obviously be a horizontal line with length equal to the width of the second filter's excitatory zone as shown superimposed on the diagram. In addition to lines of fixed length, end-stopped cells will respond well to curves that are tangent to the preferred orientation of the first-stage simple cells, and they respond well to the orientation of texture boundaries (Wilson, 1993). Although Hubel and Wiesel (1968) reported the presence of end-stopped neurons in V1, subsequent work by von der Heydt and Peterhans (1989) indicates that they predominate in the second visual area, V2.

Following V1 and V2 the cortical form vision pathway projects to V4, and finally to inferior temporal cortex (IT). Mean receptive field dimensions increase by a factor of approximately 2.5–3 from area to area within this pathway, reaching diameters of 10°–30° in IT. It was noted above that the receptive fields of end-stopped neurons must be approximately 2–3 times larger in each dimension than the simple cell receptive fields that provide their inputs in order to function optimally. Thus, the increasing receptive field size throughout the form vision pathway indicates that pooling operations are combining information over increasingly large areas. The nature of pooling in V4 was first investigated by Gallant et al. (1993). They studied macaque V4 responses to concentric and radial gratings as well as to conventional sine wave gratings. One subclass of neurons responded best to concentric gratings, while a second subclass responded best to radial gratings. Although many neurons

Figure 1 Models of (a) an end-stopped complex cell and (b) a V4 concentric unit. The end-stopped cell (a) is produced by oriented simple cell filtering followed by rectification and subsequent filtering at a different orientation. The optimal bar length and orientation for stimulation of this unit is shown. The V4 concentric model in (b) builds upon the hierarchical theme in (a) by adding a final stage of configural pooling in which responses of a concentric array of end-stopped units are summed. The three stages of the V4 model are hypothesized to occur in V1, V2, and V4.

responded to conventional sine wave gratings, few were optimized for these patterns.

Humans are extremely good at detecting concentric structure in glass patterns, and this results from concentric summation of orientation information over considerable regions (Wilson et al., 1997). A glass pattern is produced by randomly positioning pairs of signal dots such that each pair is oriented tangentially to the desired concentric structure. This produces a random dot pattern appearing to contain concentric swirls of dots. Furthermore, fMRI studies have shown that human V4 is more sensitive to concentric or radial gratings than to conventional gratings (Wilkinson et al., 2000). A quantitative model for V4 concentric receptive fields is depicted in **Figure 1**(b) (Wilson et al., 1997). The initial two stages of the model are oriented simple cells followed by rectification and orthogonal second stage filtering. As mentioned above, these model end-stopped complex cells map onto V1 and V2 physiology, and they respond to curved contours that are locally tangential to the orientation of the simple cell filter. The final stage of the V4 model consists of linear summation (Σ) of concentrically arranged curvature information from V2. This represents an example of configural pooling, as each curvature response is pooled only if it arises in a spatial subregion of the receptive field consistent with the concentric global pattern. The final V4 receptive field size is approximately three times the diameter of its V2 subunits, thus conforming to the observed receptive field size increase in the form vision pathway. Similar V4 configural pooling models may be constructed to extract radial and other structures from the stimulus, and one challenge to future research will be an enumeration of configural pooling mechanisms.

What might be the function of V4 concentric units? Several observations suggest that they may be involved in the perception of faces and other ellipsoidal shapes. First, computer simulations have shown that model V4 units can detect faces in complex scenes (Wilson et al., 2000). Second, fMRI studies have shown that the face-selective area in the fusiform gyrus responds not only to faces but also to circular or ellipsoidal contours (Wilkinson et al., 2000), thus supporting the hypothesis that analysis of head shape is a major ingredient in face perception.

Perceptual Oscillations

There are many instances of instabilities resulting in perceptual oscillations, two of the most common being the Necker cube and binocular rivalry. A third example is the Marroquin illusion in which a static, periodic dot pattern triggers the percept of flashing illusory circles (see Wilson et al., 2000). A Marroquin pattern is constructed by superimposing three square grids of dots, each rotated $\pm$ 60° with respect to one another. It is natural to conjecture that competitive interactions among V4 concentric units might be the cause of the illusory circles triggered by this stimulus. Indeed, there is physiological evidence that competition among V4 neurons forms a basis for spatial and object based selective attention (Reynolds et al., 1999).

A neural network model incorporating spatially regional competitive interactions among V4 concentric units can explain the illusory flashing Marroquin circles (Wilson et al., 2000). In this simulation V4 neural responses were represented by a variant of eqn [7]:

$$\tau_E \frac{\mathrm{d}E_n}{\mathrm{d}t} = -E_n + \frac{100\,P_+^2}{(\beta + H_n)^2 + P_+^2}$$

where

$$P = S_{\text{Marroquin}} - k \sum_{n \neq k} I_k \exp\left(-R_{nk}^5/\sigma^5\right) \qquad [9]$$

$$\tau_I \frac{\mathrm{d}I_n}{\mathrm{d}t} = -I_n + E_n$$

$$\tau_H \frac{\mathrm{d}H_n}{\mathrm{d}t} = -H_n + gE_n$$

In these equations the input P to each neuron is the response of the V4 model in **Figure 1**(b) to the Marroquin pattern, $S_{\text{Marroguin}}$ minus a spatially weighted sum of inhibitory activity I_k generated by neighboring V4 neurons, the inhibitory neurons being driven by the E cells as described by the second equation. Parameters k and σ are respectively the gain and space constant of the inhibitory region. Mathematical analysis of equations such as these shows that one further ingredient is necessary for the network to produce limit cycle oscillations: the firing rate of active excitatory neurons must decline over time (Wilson, 1999). Excitatory cortical neurons are known to contain slow hyper-polarizing currents that cause the firing rate to drop about threefold over the course of several hundred milliseconds, and this is incorporated into the mathematical model via the H or hyperpolarizing variable (Wilson, 1999). The effect of this variable, governed by g, is to increase the semisaturation constant of any active E neuron, thereby reducing the firing rate. Simulations of this network provide a good quantitative explanation of the illusory flashing circles generated by Marroquin patterns (Wilson et al., 2000). Extensions of this work suggest that models analogous to eqn [9] can also explain oscillations and traveling wave phenomena in binocular rivalry.

Conclusions and Future Directions

The low-level vision theories developed here are based on nonlinear differential equations describing firing rates (rather than individual spikes) of retinal and cortical neurons. Large-scale neural networks incorporating these principles can now be used to simulate visual processing from the retina up to V4. Although this approach certainly represents but a first-order approximation to the underlying neural activity, it nevertheless provides a solid foundation for further progress.

Many issues, of course, remain to be addressed. Key among these is the ubiquitous cortical feedback: IT back to V4, V4 back to V2, etc. One conjecture is that these connections mediate a rapid dynamical optimization of the processing circuitry based upon initial feed-forward estimates of the stimulus being analyzed: a sophisticated example of a self-organizing system (see also Self-Organizing Dynamical Systems). A second likelihood is that this feedback mediates both top-down influences on selective attention and figure-ground segmentation, which appears to involve extra-striate feedback to V1 (Lamme and Roelfsema, 2000). The future promises a cooperative interaction between theory and experiment in elucidating these and many other exciting issues.

Abstract

Visual mental imagery is the faculty whereby we can 'visualize' an object from memory. This article summarizes how damage to various brain areas can impair or not different visual perceptual or imaginal abilities. Whereas damage to occipital visual areas (striate and extrastriate) can of course produce impairments on several visual perceptual abilities, it does not seem either necessary or sufficient to impair visual mental imagery. On the other hand, damage to more anterior areas in the temporal lobe can impair visual imagery for objects, color, and orthographic material. More dorsal loci of brain damage, perhaps coupled with disconnection between the right and the left hemisphere, can induce neglect for the left part of visual mental images. Thus, there seems to be a partial overlapping between the neural correlates of high-level (but not low-level) visual perception and visual mental imagery abilities. This partial overlapping of neural resources may reflect essential differences between perception and imagery, which might be related to Sartre's distinction between more immediate and more reflective forms of consciousness.

Visual Mental Imagery and Brain Damage

Try to imagine a leopard and establish whether it has round or pointed ears. How can we revisualize an object, a face, or a color from memory? There is currently much debate on the psychological and neural aspects supporting these abilities, but we know that brain damage can disrupt them and produce particular patterns of dissociations between perceptual and imagery abilities. The first reported case of a relatively isolated deficit of mental imagery came under Charcot's observation in the Salpêtrière Hospital in Paris (Charcot and Bernard, 1883). M. X used to experience particularly vivid visual mental images for object forms and colors, which he described as being precise and glowing as reality itself. He used his ability as a mnemotist, until one day he found himself to be completely unable to recall forms and colors from memory. For example, he lost his ability to produce detailed drawings from memory, or to precisely recall poems and letters by 'reading' them in his 'mind's eye.' This deficit was relatively selective, being accompanied by only minor problems in reading and a slight decrease in color perception. There is no record concerning the potential presence of a brain lesion in M. X, but his reading problems in the absence of more elementary visual deficit might suggest left temporal damage with sparing of the occipital cortex (Bartolomeo, 2008). However, more recently Zago et al. (2011) have suggested that loss of imagery in the case of M. X may in fact have been of psychiatric origin.

Other neuropsychological studies found a frequent association of perceptual and imagery deficits in brain-damaged patients (Farah, 1988). Together with results of neuroimaging experiments in normal subjects, this evidence prompted the conclusion that visual mental imagery, much as visual perception, depended on the functioning of retinotopic areas in the occipital lobe, including V1 (Kosslyn et al., 2006). However, since the 1990s other patient studies showing double dissociations between perception and imagery abilities (reviewed by Bartolomeo, 2002) have produced a strong challenge to the perception-imagery equivalence hypothesis.

Visual Mental Imagery and the Striate Cortex

Hypotheses postulating a large anatomo-functional overlapping between visual perception and visual mental imagery assign a central role to V1 in imagery abilities (Kosslyn et al., 2006). If this is true, then patients with cortical blindness resulting from V1 damage should lose the ability to revisualize items from memory. However, neuropsychological studies have provided abundant evidence challenging this hypothesis. For example, Chatterjee and Southwood (1995) studied three cortically blind patients. Two of these patients had bilateral medial occipital damage but showed nevertheless an intact capacity for imagining object forms. In contrast, the third patient had damage extending well forward the left temporal lobe and was unable to imagine object forms. More recently, another patient was described with complete and permanent cortical blindness after bilateral damage to V1, who had perfectly preserved visual mental imagery for objects, colors, and spatial relationships (Zago et al., 2010). In contrast, another cortically blind patient, who had signs of brain hypometabolism not only in the occipital cortex, but also extending to the inferior and mesial temporal cortex, found himself unable to perform any tasks based on the visual appearance of places, symbols, objects, and animals (Policardi et al., 1996). Recently, Bridge et al. (2011) described a patient with a lesion restricted to the gray matter of the calcarine sulcus (V1). Despite near-complete cortical blindness, this patient had vivid visual mental imagery. This patient also underwent functional neuroimaging (fMRI), which demonstrated a pattern of cortical activation during visual mental imagery in occipitotemporal extrastriate areas, and in parietal and frontal regions, which was indistinguishable from normal participants. Altogether, this evidence is compelling in showing that lesions restricted to V1 do not typically produce deficits of visual mental imagery.

Another prediction resulting from the perception-imagery equivalence hypothesis is that *unilateral* occipital lesions producing lateralized visual field defects such as lack of vision in one side of the visual fields (homonymous hemianopia)

should determine corresponding lateralized deficits in visual mental imagery; i.e., impaired imagery on the blind side of the visual field. Butter et al. (1997) reported results consistent with this prediction in eight patients with unilateral field defects, whose recall of the position of previously presented dots was worse on the blind side than on the normal side. The authors concluded that visual imagery involves topographically organized visual areas of the occipital lobe. However, there are several problems with this conclusion (Bartolomeo, 2002), including the presence of lesions extending beyond the occipital cortex in at least two of the patients. A recent study on 12 patients with homonymous hemianopia (six with right-sided and six with left-sided hemianopia) (Dulin et al., 2011) challenged more directly the conclusions of the Butter et al.'s (1997) study. Using a similar test paradigm as the one employed by Butter et al. (1997), Dulin et al. (2011) found evidence for normal lateralized imagery in all the tested patients.

Visual Mental Imagery and Extrastriate Visual Areas

Even if visual mental imagery does not require the integrity of low-level visual areas such as V1, it could well rely on visual areas at a higher level of processing in the ventral cortical visual stream (Milner and Goodale, 1995; Mishkin et al., 1983). However, the precise level of visual processing putatively important for visual mental imagery remains uncertain. Bartolomeo et al. (1998a) described a striking dissociation between impaired perception for high-level visual attributes and preserved imagery in a patient (Madame D) with bilateral extrastriate lesions, at the borders between the occipital and the temporal lobes. After the occurrence of her lesions, Madame D had severely impaired visual perception for object form (visual agnosia), words and letters (alexia without agraphia), colors (cerebral achromatopsia), and faces (prosopagnosia). However, her visual mental imagery for the same visual entities was perfectly preserved. She produced plausible drawings from memory, while being unable to identify her drawings on subsequent testing. Madame D had thus intact mental imagery for the very same visual entities that she could not perceive. More recently, Moro and collaborators (2008) made a detailed report of the complementary dissociation in two patients with traumatic brain injury, who had impaired visual mental imagery with reasonably preserved perception. In both cases, there was an involvement of the left temporal lobe in the absence of visible damage to the occipital cortex.

These and many other case reports (Bartolomeo, 2002) challenge the hypothesis that visual occipital areas are necessary to visual mental imagery, and suggests instead that extensive damage to the left temporal lobe is crucial to observe deficits of visual mental imagery, at least for object shape and color and for orthographic material. Since this conclusion was proposed (Bartolomeo, 2002, 2008), it has received further support from several more recent studies of patient with occipital damage and cerebral blindness (Bridge et al., 2011) or homonymous hemianopia (Dulin et al., 2011). An interim conclusion at this point could thus be that regions in the occipital cortex are not necessary to visual mental imagery abilities; however, the possibility remains open that areas in more anterior locations along the ventral visual processing streams, such as the temporal lobe, might be important for these abilities.

Domains of Visual Mental Imagery: Color, Words, and Space

Visual mental imagery is not a unitary, undifferentiated faculty. Neuropsychological evidence suggests the possibility to distinguish at least five kinds of visual entities whose imagery can be independently affected by brain damage: shapes of objects, colors of objects, faces, orthographic material, and spatial relationships (Goldenberg, 1993). We will present here a selection of evidence concerning the neuropsychology of mental imagery for three of these domains: color, orthographic material, and spatial arrays.

Visual Mental Imagery of Color

Color processing is a privileged domain for the study of visual imagery abilities, because it has more chances of requiring genuinely visual processes than the other domains, whose spatial characteristics may authorize the use of nonvisual strategies (Farah, 1988). After several early reports of patients with an association of impaired color perception resulting from brain lesions (cerebral achromatopsia) and loss of color imagery (Damasio, 1994), further case descriptions pointed out the possibility of normal color imagery in achromatopsic patients, and of normal color vision with loss of color imagery (Bartolomeo, 2002). For example, soon after her strokes Madame D (Bartolomeo et al., 1997) complained to see the world in shades of gray or, later on, in reddish-brown nuances, but could form vivid mental images of colors and even perform subtle hue discriminations between imagined colors. Miceli and coworkers (2001) reported a detailed description of patients PCO and IOC, with normal color perception but impaired color knowledge. These patients could not attribute the correct color to objects, or select the correct crayon to color them. Of note, IOC, but not PCO, had apparently normal knowledge of the form and function of objects. Although the issue of mental imagery was not explicitly addressed in this study, the pattern of performance of these two patients strongly suggests a selective deficit of visual mental imagery for colors for IOC, and an impairment of color and form imagery for PCO. PCO had suffered from encephalitis resulting in bilateral lesions (more extensive on the left than on the right) of the temporal pole and the inferolateral temporal regions (middle and inferior temporal gyri), prefrontal convexity, and orbital gyri. Damage was less extensive in the parietal lobe and the superior-rostral insula. Both hippocampi were atrophic. IOC had lesions in the calcarine cortex, the lingual gyrus, the isthmus and the adjacent cingulate gyrus, the parahippocampal gyrus and the rostro-medial part of the fusiform gyrus, including part of the ventral portion of the temporal pole, with left hippocampal atrophy, as a consequence of a stroke in the territory of the left posterior cerebral artery. Interestingly, a control patient reported in the same study, SLA, who had more posterior lesions in the left

hemisphere involving the posterior part of the lingual gyrus, the cuneus, and the calcarine cortex, with largely spared temporal cortex, had right homonymous hemianopia but no cognitive impairment. In particular, SLA had normal knowledge of colors. Thus, an extensive damage of the left temporal lobe seems both necessary and sufficient to produce deficits of color imagery.

Visual Mental Imagery of Orthographic Material

Literacy induces peculiar modifications of the visual system (Dehaene et al., 2010). In literate people, left posterior brain damage can disrupt the processing of visually presented letters and words in the relative absence of other deficits (and notably, with preserved writing), a disorder known as alexia without agraphia or pure alexia (Bachoud-Lévi and Bartolomeo, 2003; Dejerine, 1892). We have already mentioned the case of Madame D, who, despite being profoundly alexic and incapable to identify even single letters without errors (Bartolomeo et al., 1998b), could perform at ceiling difficult tests concerning the visual appearance of letters and words (Bartolomeo et al., 1998a). For example, she could easily answer questions such as: imagine the letter M. Cut it into half vertically. Drop off the right side and turn the remaining part upside down (the answer is V). A similar dissociation between impaired perception and preserved imagery also held for numbers in this patient. For example, Madame D was unable to recognize visually the number 6, but described it as 'a half circle open toward the right, making a loop at its bottom.' Complementary evidence concerning the neural bases of visual knowledge of orthographic material came from the description of another pure alexic patient, VSB. In addition to his reading deficit, VSB was found to suffer from a selective deficit for visual mental imagery of orthographic material, or loss of letter shape knowledge (Bartolomeo et al., 2002). In this patient, an extensive left temporal–parietal lesion severely impaired reading, whereas writing was relatively preserved. At variance with other pure alexic patients described in the literature, VSB claimed to have become unable to mentally visualize letters and words. Indeed, his performance on a series of tests tapping visual mental imagery for orthographic material was severely impaired. In the present framework, the extensive left temporal damage suffered by VSB may account for his mental imagery deficit. However, allowing VSB to trace each item with his finger dramatically ameliorated performance on the same tests. Visual mental imagery for nonorthographic items was comparatively spared. The pattern of dissociation shown by VSB between impaired visual mental imagery and relatively preserved motor-based knowledge for orthographic material lends support to the view that separate codes, respectively, based on visual appearance and on motor engrams, may be used to access knowledge of the visual form of letters and words.

Damage to domain-specific regions (Kanwisher, 2000) or circuits (Epelbaum et al., 2008) in the ventral temporal lobe might thus contribute to the occurring of selective deficits of distinct domains of visually based knowledge. However, it remains uncertain whether there is a strict overlapping of perceptual and imagery functions within the same high-level visual regions in the temporal lobe (Rich, et al., 2006), or whether nearby but distinct regions are important for these different abilities.

Imaginal Neglect

A particular class of deficits of spatial imagery concerns the impaired ability to conjure up or produce a complete and symmetrical description of an imagined scene. Patients with damage to the right hemisphere may behave as if the left part of the world does not exist anymore, thus showing signs of left visuospatial neglect (Bartolomeo, 2007; Halligan and Bartolomeo, 2012). About a third of these patients may also show neglect for the left part of their mental images (Bartolomeo et al., 1994). These patients may omit to mention the left side of the mental space when describing places from memory, thus demonstrating 'imaginal' neglect (Bisiach and Luzzatti, 1978). Not all patients with visual neglect show imaginal neglect. A possibility to explain this dissociation is that an important aspect of neglect is that patients' attention is 'captured' by right-sided objects and cannot easily disengage from these objects to explore the remaining space; however, imagined details may have less attention-capturing power than real ones, thus decreasing the possibility to observe imaginal neglect (Bartolomeo et al., 1994). Nevertheless, imaginal neglect can also occur in the absence of signs of perceptual neglect, either at the onset or, perhaps more commonly, as a result of selective compensation for the perceptual aspects of the syndrome. Patients often learn with time (and possibly the help of people around them) to explore more thoroughly their visual environment. However, compensation may be more difficult to obtain in the more abstract imaginal domain, which is rarely the object of rehabilitation or of more informal reminders to 'look to your left' (Bartolomeo and Chokron, 2001). Thus, similar to other domains of visual mental imagery, several studies have reported the existence of double dissociations between imaginal and perceptual neglect (Anderson, 1993; Beschin et al., 1997; Coslett, 1997; Guariglia et al., 1993; and Ortigue et al., 2001).

However, the study of imaginal neglect raises peculiar methodological problems. Often, very different task are used to evaluate spatial perception and spatial imagery. In particular, in several studies paper-and-pencil tests were used to test perceptual neglect and description from memory was used to test imaginal neglect (Bartolomeo et al., 1994; Rode and Perenin, 1994; Rode et al., 2007). Moreover, description from memory might rely more on verbal semantic memory than on visual imagery, and thus produce symmetrical descriptions even in the presence of imaginal neglect (Rode et al., 2004). To encourage the use of a visual mental strategy, a response time 'geographical' test was devised (Bartolomeo et al., 2005), with strictly comparable perceptual and imaginal conditions (Bourlon et al., 2008, 2011). In different tasks, participants either saw towns/regions on a map of France or heard their names, and pressed one of two keys according to the stimulus location (left or right of Paris). The results obtained with these tasks confirmed the rarity of imaginal neglect with respect to perceptual neglect.

In a recent case report of imaginal neglect (Rode et al., 2010), structural and diffusion MRI demonstrated damage to

several white matter tracts in the right hemisphere and to the splenium of corpus callosum (the principal connection between the two brain hemispheres). The same study reported on a second right-brain damaged patient, who showed signs of perceptual but not imaginal neglect, and had damage to the same intrahemispheric tracts; the callosal connections, however, were spared. Imaginal neglect might thus result from the association of frontoparietal dysfunction, which impairs orienting toward left-sided items (Bartolomeo et al., 2007) and additional posterior callosal disconnection, which prevents the symmetrical processing of spatial information from long-term memory.

In clinical settings, drawing from memory is often used to assess imaginal abilities and then directly compared to drawing copying. However, the visual feedback in drawing test may influence the patient by inducing an attentional capture of the right-sided details the patient had just drawn (Chokron et al., 2004). To address this issue, drawing without visual feedback was proposed, e.g., while blindfolded (Chokron et al., 2004) or using a pen that leaves no visible traces on the sheet (Cristinzio et al., 2009). While in general patients demonstrate more neglect with visual feedback than without visual feedback (Chokron et al., 2004), thus confirming the attention-capturing effect of right-sided visual items (Bartolomeo et al., 1994), one recent case report (Cristinzio et al., 2009) showed the opposite effect: the patient had more neglect without than with visual feedback, perhaps as a consequence of concomitant impairment of working memory, which prevented the patient from remembering what he had already drawn. To summarize, one possibility to account for the rarity of imaginal neglect is that this form of neglect might depend on deficits of top-down processes, such as endogenous attention or active rehearsal of spatial knowledge, that are less impaired than exogenous attention in patients with perceptual neglect (Bourlon et al., 2011).

Assessment of Visual Mental Imagery

How to test for visual mental imagery abilities in brain-damaged patients? The usual strategy, borrowed from experimental psychology studies in normal individuals, is to ask patients to perform tasks that most likely cannot be resolved with simple access to (nonvisual) semantic information. For example, when exploring visual knowledge of colors, one can ask questions about the typical color of objects, with the precaution of avoiding items whose color can be retrieved by using nonvisual associations (e.g., red–blood, white–snow) (Bartolomeo et al., 1997; Beauvois and Saillant, 1985). A recent case report (Zeman et al., 2010), however, raises the disquieting possibility that at least some of these tasks can be correctly performed in the absence of the corresponding 'quasi-visual' phenomenological experience, which should be typical of visual mental imagery. These authors described a patient who performed normally on mental imagery tasks while negating to experience visual mental images. During attempted imagery, this patient, who had no visible brain lesion, showed reduced fMRI activation in a network of posterior regions, while activity in frontal regions was increased compared to controls. A possible conclusion could be that V1 activity is crucial to the phenomenological qualities of mental imagery. Against this conclusion, however, the recently described patient with V1 damage mentioned before (Bridge et al., 2011) did report experiencing vivid visual images of faces and houses, while demonstrating extrastriate and frontal activations on fMRI.

"The Batterie Imagination et Perception" (BIP)

A standardized paper-and-pencil battery of tests has recently been developed in order to assess perceptual and imaginal deficits in patients with brain damage (BIP, Bourlon, et al., 2009). The BIP, which currently exists in French (Bourlon et al., 2009) and Italian language (Antonietti et al., 2008) versions, examines distinct domains of visual mental imagery and visual perception abilities such as object form and color, animals, orthographic material, numbers, faces, and spatial relationships. It comprises two parts: one composed of 14 tests assessing mental imagery, another composed of eight tests assessing various visual perceptual abilities. The BIP was designed to investigate associations and dissociations between perceptual and imaginal deficits in patients and thus provide evidence relevant to the debate concerning the neural bases of visual mental imagery. Here follows a short summary of the tests used.

The imagery section of the BIP consists of tests of animal comparison (participants mentally compare the size of an animal to that of a goat) (Kosslyn et al., 1995); mental representation of physical details (establish whether the ears of a determined animal are round or sharp) (Sheridan and Humphreys, 1993); object comparison (determine from memory which of the two items named by the examiner is bigger); morphological discrimination (compare from memory pairs of objects, animals, or fruits that are morphologically similar, and mention the difference in their visual appearance); mental representation of objects (recall from memory the typical shape and the orientation of objects); recall of object color (recall the typical color of objects mentioned by the examiner) (Bartolomeo et al., 1997); color comparison (determine which of the two objects mentioned by the examiner is lighter in color) (De Vreese, 1991); mental representation of numbers (decide whether numbers mentioned by the examiner have closed loops (e.g., 8) or not (e.g., 2)) (Coltheart et al., 1975); mental construction of letters (identify upper-case letters after having mentally built them following oral instructions) (Behrmann et al., 1994); mental representation of letters (in the first part of this test, participants have to imagine lower case letters named by the examiner and decide whether they appear in the space line, exceed above space line or beneath space line (Weber and Castleman, 1970); in the second part, participants have to state from memory whether upper-case letters named by the examiner contain any curved lines or not) (Coltheart et al., 1975); mental representation of words (decide if words named by the examiner contain one or more letters with an ascender (t, l, d), a descender (j, p, y), or neither (m, e)) (Weber and Castleman, 1970); mental representation of faces (answer questions about the shape of the nose (thin–large), and the

shape of the lips (thin–fleshy) of famous faces) (Bartolomeo et al., 1998a); mental representation of spatial relationships (evaluate the position of imagined dots) (Butter et al., 1997); and modified o'clock test (establish the position of the hands of an imagined clock for a verbally given hour) (Grossi et al., 1993). The perception section of the BIP consists of analogous tests, visually presented stimuli.

Conclusion

Mental imagery abilities draw on particular sorts of conscious processes, whose phenomenological quality can be distinguished from visual perception (Sartre, 1936), and is closer to visual memories. For example, you can be surprised by a visual perception, but not by the mental image that you conjured up (Sartre, 1940). Another crucial difference between mental images and their 'real' counterparts is that mental images are based on active processes of reflective consciousness, as opposed to the more immediate character of perception. As a consequence, imagery abilities make us ontologically free from the constraints of reality (Sartre, 1940), as well as from its influence on elementary sensory processing (Mesulam, 1998). In this sense, mental imagery is a central feature of our being human. Lesion neuropsychology provides key causal evidence to establish its neural underpinnings.

Visual Images in the Media

John Huxford, School of Communication, Illinois State University, Normal, IL, USA

Abstract

This article offers a review and assessment of the polemics surrounding the nature of the visual image (i.e., a reproduced sight) in the media (mass-produced communication), and of its social implications. The author explores the intellectual history of the debate, which is most typically advanced as an opposition between the qualities and effects of the word, or text, and of the image. The discussion is tracked across three key areas: child literacy and education, commercial and political persuasion, and issues surrounding the news. It is also suggested that in an era when the image is seen to have gained ascendency over text, digital tools and the power of the Internet bring potent new influences on the way we create, consume, and comprehend visual images.

The world is filled with visual images. Images appear on television and movie screens, billboards, posters, magazines, newspapers, and computer monitors. While, as a specific field of academic study and teaching, visual communication is little more than 50 years old, the properties and impact of the visual image have been the subject of research for centuries across a range of academic disciplines. In recent years, the emphasis has moved away from theories of art toward a psychosocial perspective that draws on research from semiotics, branches of psychology, sociology and communications, and cultural theory.

In this article, the discussion will focus on three key areas: child literacy and education, commercial and political persuasion, and issues surrounding news, as well as on the repercussions of digital imagery and the way that the power of cyberspace is changing the social role of visual communication.

The Age of the Image

Increasingly, it is argued that the word, once the dominant medium, is being supplanted by the image. Civilization has taken, in W.J.T Michell's phrase, a 'pictorial turn' (Mitchell, 1994: pp. 2–3). As Kellner suggests: "We are living in one of the most artificial visual and image-saturated cultures in human history, which makes understanding the complex construction and multiple social functions of visual imagery more important than ever before" (2002: p. 81).

In earlier centuries, the balance between verbal and visual representation strongly favored the word. Text dominated, while images in books typically served in a subsidiary role as illustrations. However, this status quo was challenged by the emergence of the photographic process in the nineteenth century, with photographs then spreading into newspapers and advertisements. Film accelerated the process with the development of a series of audiovisual technologies, including movies and television, tipping the balance between word and image in favor of the latter.

Today digital imagery and streaming video in cyberspace have added new dimensions to our ever-developing and increasingly complex visual culture. Text and images interact in new ways in the multimedia terrain of the Internet, reigniting the long-standing debate over the properties and functions of the visual versus those of the word.

Visual Images versus the Word

There has long been debate over the social implications of the image. Often this has centered on controversies that surround certain visual media; most prominently, racial and gender stereotyping, sexually explicit material, and violence as depicted on television, film, the Web, and in video games. However, this debate has also been advanced as an opposition between the qualities and social effects of the word or text, and those of the image, with the former typically being privileged over the latter.

History of the Debate

Whichever medium may be the most ubiquitous, the premise on which this debate turns has always been the supposed superiority of text over image, a bias informed by an intellectual tradition that stretches back centuries. (For a detailed discussion, see Stephens, 1998.) The Bible, in associating the Word with creation in Genesis while forbidding the production of the 'graven image or any likeness,' has long been used to support this presumption. Even as the image has established itself at the center of Western culture, writers and philosophers from Plato to contemporary thinkers have remained critical of the qualities and effects of the image compared to those of the word.

This intellectual antipathy is prompted by a series of overlapping concerns. Partly, it is founded on a long-standing suspicion of *verisimilitude*. In one view, such a capturing of likeness evokes a high degree of 'truth.' It is this perspective that typically reflects a traditional, although now contested, history of art as the progress of visual reproduction toward an ever more accurate reflection of the natural world, an ideal established by the Romans, and one that finds its most perfect expression in the photographic process.

However, verisimilitude has also driven a more negative perspective; that what the visual image offers is not truth but seductive illusion. A painter, Plato wrote, can deceive 'children

and fools' with the 'imitation of appearance,' instead of bringing 'truth' or 'real things' (1956: p. 463). Substantively, this argument remains the root of one strain of criticism laid against television and movies, that their illusionary realism may offer an ideal vehicle for propaganda.

A second charge leveled against the visual image is that, with the growth of technical reproduction, images devalue the objects they represent. The uniqueness of the original is lost in the deluge of visual copies. This argument is perhaps most acute when what is being reproduced are images of cherished buildings, statues and landmarks, and most especially, works of art. When the Mona Lisa becomes a common sight in the everyday world beyond the louver – for example, on T-shirts and advertising hoardings – the 'quality of its presence,' in the words of Walter Benjamin, is "always depreciated" (1969: p. 221).

A third charge involves the long-held belief that the image speaks more directly to the emotions than to the logical mind. Aquinas argued that images "excite the emotions more effectively aroused by things seen than by things heard" (cited in Freedberg, 1989: p. 162). This rousing of emotions is seen as making the problems surrounding pornography and the visual depiction of violence all the more acute.

Finally, the image's accessibility may distract the populace from the more cerebral merits of the word, be it the religious tract, improving essay, or newspaper text.

Visual Images and Child Literacy

If there is unease that the image is replacing the word for society in general, this concern is heightened in debates over child literacy. At different times, anxiety has centered on the presumed ill effects on children's reading abilities and habits of a series of visual media, including movies, comic books, and video games. However, most commonly criticized is television. Researchers have offered a number of hypotheses concerning the effects of television on child literacy and weighed the empirical evidence for each.

A *stimulation* hypothesis argues that there is no conflict between images on television and words in print because watching television stimulates or improves reading in the young. This theory, although not widely held, rests largely on studies concerned with the reading of a book based on a television show after watching the program, or more generally, on children being prompted by television to research an interest. However, in a study of the juvenile book market, only a small percentage of children reported reading a book after seeing or hearing of it through television. Similarly, the findings from other studies imply that any interests that are aroused by television tend to be short-lived.

More systematically studied are variations of a *reduction* hypothesis, where the consumption of television is predicted to have a negative impact on reading. There are five common variations of this hypothesis. First, a *displacement* hypothesis argues that television viewing takes time away from reading. However, studies have shown no conclusive evidence of this, indicating instead that time given to reading, although always scant, has remained remarkably stable.

Second, the *passivity* hypothesis argues that television viewing causes children to become mentally indolent and so less inclined to read. Although studies have shown that television does require less mental effort than reading, it is argued that synthesizing visual and audio information engages children in a process that is active, not passive. Third, the *retardation* hypothesis, an associated theory that argues television viewing deteriorates the brain, is seen as implausible for the same reason.

A fourth variety of reduction hypothesis is *concentration deterioration*, which suggests that a child's ability to concentrate is weakened by television. This too, although popular among critics, has found little scientific support.

Finally, *anti-school* hypotheses argue that children come to expect school to be as entertaining and immediately gratifying as television programs, and when it fails to meet these expectations, pupils lose motivation. Once more, the evidence for this is contradictory and inconclusive.

Visual Images in Education

In contrast to the attribution of negative effects to television viewing, some educationalists have called for the visual image to play a larger role in school curriculums which, traditionally, have been dominated by the word. Despite the criticism of television in general, some educational shows – such as 'Sesame Street' – have achieved strong reputations.

More recently – and despite the negative issues surrounding some games – there has been increasing interest in the potential of video games as educational tools. Some scholars have argued that such games may teach not only specific educational content but also foster the ability to learn by stimulating cognitive development. Proponents point to the focus on problem solving that is central to many games, and it has been argued that video games may even encourage children to develop a basic understanding of scientific methodology, in which hypotheses are formed and tested, as they seek to understand and manipulate the game world. (For a detailed examination of these issues, see Brown, 2008.)

In broader terms, this move toward the educational value of images may represent a belief in the benefits of acquiring what has been termed 'visual literacy.' The view is that irrespective of content, engagement with visual media may lead to the development of mental skills applicable beyond the understanding of the medium itself. To some extent, this argument is predicated on the widely influential work of Howard Gardner who, in developing a theory of 'multiple intelligences,' argued that different modes of communication are beneficial to the development of different types of intelligence.

However, the theory that visual imagery may encourage both specific cognitive development and a distinctive worldview is more generally a reflection of similar beliefs regarding textual and verbal communication, as expressed, most notably, by linguists Edward Sapir and Benjamin Lee Whorf. The perspective may also be traced to theories associated with Marshall McLuhan, who links cognition to the technical characteristics of varying media.

From this perspective, it is suggested that television-based teaching may have a positive effect on a number of areas of cognition, including the formation of a distinctive worldview,

analytic reasoning, and spatial intelligence: the ability to envision mentally, for example, what a shape might look like from various angles. It is also suggested that exposure to certain visual media, such as advertisements that employ metaphors, may encourage and develop abstractive and analogical thinking.

However, it is argued that because images primarily function as *analogs* of reality and are so less inclined to divide the perceived world into particular categories in the manner characteristic of language, the development of a specific worldview through exposure to visual imagery appears unlikely. (This is not to say that the *uses* to which the visual image may be put – e.g., to depict violence on television – may not have significant impact on one's worldview.)

Similarly, it is judged improbable that engagement with visual forms will enhance a viewer's skills in analytic thinking, since images lack many of the propositional elements of language (for example, it is difficult to make statements in the negative through images, e.g., 'there is no more ice cream'). While a stronger case may be made for the connection between visual imagery and spatial intelligence, evidence for these benefits is also weak. Finally, it is argued that aspects of abstractive or analogical thinking may indeed profit from viewing certain visual material, although the argument remains controversial (see Messaris, 1994 for a full discussion).

More generally, there is a growing body of opinion that, rather than teaching new cognitive skills, the representational conventions of images are founded on informational cues that people *routinely* learn to interpret through their visual experiences in real life. This calls into the question the very existence of a distinctive 'visual literacy' based on cognitive abilities acquired through exposure to mediated imagery.

Properties of Visual Images

Overall, there is scant evidence then, that visual images – most typically in the form of television – are either detrimental to child literacy, or significantly contribute to distinctive cognitive development.

However, it is clear that the image does possess distinctive qualities. Peirce's classification of signs into iconic, indexical, and symbolic (Pierce, 1991) is seen as an important key to these properties. Images that bear a resemblance to some aspect of reality are examples of *iconic* signs. At the same time, the photograph may be defined as an *index*; a sign that has some physical connection to the object or event to which it refers, (such as fingerprints or footprints) since it is produced by the physical effect of reflected light.

These features clearly set the image apart from the word. Iconic signs have little role in language and indexicality is entirely absent. Conversely, the visual image would normally not rely on the type of arbitrary conventions that link signifier (representation) with signified (what is represented) in the manner that constitutes the symbolic mode most characteristic of language.

Another crucial distinction can be made between words and visual images. Whereas verbal communication possesses detailed conventions governing word order (or syntax) that facilitate the linking of concepts, there is no such formal convention for combining images into larger meanings, although those who work with images, such as artists, may develop their own. Images exhibit what is termed 'syntactic indeterminacy' that increases their ambiguity as carriers of meaning (Messaris, 1997).

These distinct features have important consequences for the roles that the visual image plays within society. While it is difficult for images to convey precise *statements* about the objects they represent (e.g., 'the man no longer enjoys sarcasm'), still the image's characteristic iconicity, together with less pronounced but flexible symbolic properties, have allowed the medium to convey certain, descriptive information with a precision unmatched by words. For example, a range of scientific fields have been advanced through the use of detailed depictions and diagrams.

Equally, the visual image has been a boon in the development of user-friendly computers, where iconic representations, such as scissors and folders, have been used to replace lines of text. At the same time, photographic indexicality has become a vital component in the creation of historical records.

However, these properties may also have troubling consequences.

Visual Images and Persuasion

Iconicity, indexicality, and syntactic indeterminacy bring distinctive properties to visual persuasion, be it set to commercial or political purposes. In an extensive study of these issues, Messaris (1997) offers a broad range of devices through which the advertising image may engage attention and mold attitudes. Iconic representations of physical appearance and interpersonal behavior may reproduce real-world visual cues associated with a series of emotional responses; including sexual interest and excitement. This prompting of emotion is central to advertising strategies that seek to associate positive feelings with the possession or consumption of products (see, for example, Williamson, 1978). Further, iconic devices that manipulate the viewer's point of view (such as close-ups or high and low angles) can incite a series of other responses, including curiosity and trust.

The ability of iconicity to communicate information quickly and with relatively little mental effort may contribute to another advantage the image may have in persuasion. Some cognitive psychologists believe that visual images are typically processed peripherally – rather than centrally – in ways that may decrease the likelihood of viewers engaging their full critical and analytical faculties, especially when the speed of the message leaves little time for reflection.

The 'truthfulness' implied by indexicality is also a critical ingredient in visual persuasion whenever a photographic image is offered as proof of an advertiser's claims. However, visual images may readily be made to lie through the application of a wide range of techniques, from the staging of photographs to airbrushing to improve appearances. Moreover, digital technology has become a powerful aid to those who would practice such visual deception.

Finally, the syntactic indeterminacy of the image may also have important consequences that make it more useful in persuasion than the explicit meanings offered by words. For example, advertisers may take advantage of this property to

imply associations or statements that they would be unwise to state verbally (such as the association of cigarette smoking with healthy activity).

The implications of these properties have led to a heightened attention to the exploration of image production and the messages imbedded within them, most commonly through the perspective of critical analysis. Critical cultural analysis views society as a 'contested terrain,' a battleground for "domination and hegemony between competing gender, race, sex, ethnic, class, and other forces" (Kellner, 2002: p. 85). From this perspective, "codes of power are embedded in all visual images to varying degrees" (Sperling, 2011: p. 28).

These concerns focus on a range of issues and forms of media, for example, the sexual objectify of women in music videos, celebrity gossip magazines, and video games.

Two of the most debated arenas, however, remain the persuasive effects of imagery in political and commercial communication, and in the news.

Visual Images and Politics

While political advertising has existed, in its modern form, since at least the 1820s, television ads have now become a primary source of political information. Television has been accused of having a number of detrimental consequences for the political process. These include, in a political equivalent to the displacement theory associated with child literacy (see above), distracting the populace from civic involvement. However, the area of most concern with regard to the visual image is its effects within political advertising and televisual campaigning.

The potency of the visual image in political persuasion is thought to have been most graphically displayed in a debate between Richard Nixon and John F. Kennedy. It is reported that the majority of those who saw the 1960 debate on television judged Kennedy the victor, while most who listened on radio thought Nixon had won. Typically, this result has been taken to indicate that the more attractive image that Kennedy presented was the deciding factor, even though other influences have been offered – including the possibility that it was radio that may have favored Nixon's patterns of delivery, while exaggerating Kennedy's Boston accent in a manner that repelled listeners (Schudson, 1995).

The use of visual imagery for persuasive purposes becomes most intense in political advertising. Although the public is becoming more skilled at 'reading' visual cues, it is argued that viewers usually do not take the time to consider the way these cues may be attempting to manipulate their attitudes, making the visual element of political ads the most crucial.

Political advertisements use many of the same visual strategies as their commercial counterparts, although often exhibiting a strong reliance on iconic visual effects. Patriotic appeals are common in the political advertisement or campaign, and the use of certain visual symbols – including the national flag – has been found to be especially prevalent. Equally, the use of family imagery, such as images of spouses and of children, remains common.

The iconicity of visual imagery has been held responsible for other political strategies that accentuate appearance over content. Many make extensive use of devices that appear to be modeled on people's real-world experiences of interpersonal space. For example, politicians interviewed on television will typically turn toward the camera, and therefore toward the viewer, in order to imitate the real-world appearance of a direct and candid approach. Similarly, the use of color to create emotional impact is widespread in political advertisements. Bright colors are used to connote positive images, while gray or black and white are frequently employed in attack ads to help prompt a negative response.

Visual Images and the News

Equally controversial has been the influence of the visual image in news. The entry of the image into an arena that had traditionally been the province of the word was originally viewed with consternation, both by journalists and by many outside of the profession, as the use of visual material developed from artwork through woodcut engraving to early photographs. Visual images continued to be regarded as a medium that bypassed the reasoning mind and, as such, appeared to threaten journalism's Enlightenment heritage. While the photograph was held in higher esteem in the picture magazine, this had little impact on its critics.

Yet at the same time, the photographic record, as metaphor, as well as in practice, came to underpin the journalistic enterprise. By the mid-nineteenth century, there was widespread typification of the newspaper as a 'daguerreotype' (an early camera) of the social and natural world, with the indexicality of the process being used to exemplify, and give credence to, claims of journalistic objectivity (Zelizer, 1998: p. 9).

However, Photoshop and other digital techniques have made it increasingly easy to falsify photographs, with such practices finding their way into the news. More broadly, critics have argued that the apparent immediacy of the news photograph works to render invisible the human agency involved in its production. In practice, every image is subject to selection, interpretation, and, often, alteration as it works its way through the news process.

The news photograph embodies the perspective of the photographer who selects a particular camera angle; the page designer or editor who frequently selects one shot from a large number taken of an event and who may then crop the image; and the headline or caption writer where the photograph will be combined with, and interpreted through, text, while simultaneously being bounded within the newspaper's policy on how photographs may be deployed. At each stage the image is made to conform to a certain narrative structure – a news angle or theme – with its meaning inevitably being colored and manipulated by that association. As Stuart Hall observes: "News photos operate under a hidden sign marked 'this really happened, see for yourself.' Of course, the choice is this moment of an event as against that, of this person rather than that, of this angle rather than any other. Indeed the selection of this photographed incident to represent a whole complex chain of events and meaning, is a highly ideological procedure" (Hall, 1973: p. 241).

Similarly, in response to claims that the photography offers a transparent 'codeless' window on the world of newsworthy events, scholars have pointed to the use of photographs, in all news media, as being a practice based on cultural codes of understanding (such as an eagle representing freedom in America), as well to the connotative properties inherent in the practice itself. Roland Barthes (1977), among others, has argued that the photograph fulfills not only a denotative (or referential) but also a connotative (or interpretive) function, which undermines its claim to be unmediated truth.

Visual symbolism is frequently used in news to carry messages that stretch far beyond the photograph's referential qualities, with such techniques used to provide photographic validation of "abstract issues and qualities that cannot, in the normal sense, be validated visually" (Huxford, 2001: p. 45). Huxford offers three classifications of photographic symbolism routinely employed in the press on both sides of the Atlantic; *temporal*, in which time frames are evoked and utilized within the newspage; *metaphorical*, where analogical associations are employed; and *synthetic* which entails gross distortions of reality.

In all these ways, the news photograph, be it on the page, computer screen, or in broadcast film, may be far from either 'neutral' or 'objective.'

More recently, the focus of research has shifted away from issues surrounding the veracity of the news photograph, and toward the social and cultural functions that news photography may fulfill. This development highlights the ritual work of journalism in social life, specifically its role in creating and sustaining both communal and individual identities. The unifying work of ritual and of ritualistic journalism becomes particularly crucial when death or destruction threatens the social order. Research following this line of inquiry has included Dayan and Katz's exploration of the live coverage of events of significant social meaning; what is described as the 'contests,' 'conquests,' and 'coronations' that relate to one or more of the core values of society (1992: p. 199). Similarly it is argued that news images may be translated into 'lived images' during community ritual, being appropriated and reworked in ways that may empower and heal the community. For example, the striking and dramatic news imagery that was a central focus of the attack on the United States in 9/11 later reemerged in new ways in local carnivals and parades, with floats featuring pictures and models of the Twin Towers restored to their former glory (Coonfield and Huxford, 2009).

Digital Images

The ascendency of the image and the controversy over its effects in such areas as education, politics, and news have been accelerated and intensified by the rise of digital media.

While the Web has, arguably, given fresh impetus to text and allowed the word and image to interact in new ways, Web designers frequently give more space and visual weight to imagery. Moreover, streaming video is gaining increasing importance on the Web as technology and bandwidth improve.

A significant aspect of this new digital frontier is the manner in which it has fostered expertise in creating and manipulating digital imagery, turning users from passive viewers of images into active participants. The development of digital photography has prompted a substantial leap in the number of pictures being produced. By 2004, 28 billion digital photos then were being taken annually in the U.S., 6 billion more photos were shot on film, even though twice as many people owned film-roll cameras than digital (Murray, 2008: p. 152). The downloading and placing of such photographs on home pages, social networking sites, and blogs is now ubiquitous, while many individuals are also producing their own video clips, segments of animation, and even short movies. At the same time, a host of online communities that hone and spread this digital expertise have emerged in recent years. As Sperling argues, "Today's students also form individual identities and act online; they are at home with the Interweb's visual architectures and intellectual platforms; and they actively embrace the informality of its connections, its unstable transactions, the fluidity of its borders, and its shifting and disorienting discursive spaces" (2011: p. 28).

While the Web has been described as a 'digital utopia' (Rosen, 2001: p. 318), many of the issues surrounding the deceptive and potentially damaging effects of visual representation have followed images into cyberspace. Digital media has provided those who would perpetrate visual fakery with an arsenal of increasingly subtle and effective tools. At the same time, the range of visual networks through which today's online users move and the speed of those operations raise the likelihood that many images will register subconsciously, as unexamined beliefs and assumptions are prompted and absorbed.

However, the apparent vulnerability of the digital audience to visual trickery has been questioned. Some scholars argue that the key feature of today's 'post-photographic age,' where the digital image has replaced traditional emulsion-based photography, is that all pictures are seen as artificial representations of reality and are thus treated with increasing skepticism (e.g., Farid, 2009: pp. 42–44). Others are less sanguine. Messaris (2012), while acknowledging that the Web's digital networks have made it easier for the detection of visual manipulation to be publicized, also points out that awareness of the likelihood of digital manipulation does not necessarily translate into an ability to detect its use in specific instances.

Examples of digital manipulation of photographs that go undetected can be found in two key areas discussed in this article: political communication and news coverage. For instance, one experiment staged at Stanford University at the time of the 2004 Presidential election has implications for political persuasion. In this, photographs of the facial features of test subjects were subtly combined with the faces of either Republican George Bush or Democrat John Kerry. The subjects were then asked to make a preference between the photographs of the two politicians.

Researcher Jeremy Bailenson and his colleagues found that while the choices of highly partisan voters were unaffected by this manipulation, among those with less certain political preference the facial 'morphs' had the effect of swinging people's choices in the direction of the morph that included their own facial features. This held true even though the subjects demonstrated no conscious awareness of the manipulation (Bailenson et al., 2008).

Similarly, there are instances in news, as Messaris points out, when even journalists have been fooled by digitally doctored photographs. For example, when a fake photograph of the dead Osama bin Laden was posted online by unknown sources, the image was used on a number of well-regarded news sites before being exposed as a hoax.

Summarizing this debate, Messaris suggests, "In addressing this issue a researcher would have to go beyond the methodology of traditional surveys. The evidence would have to come from the examination of people's spontaneous reactions to images. Without a systematic look at such data, all claims about the effects of digital media on the public's attitudes towards images will necessarily remain highly conjectural" (2012: p. 10).

Abstract

When you open your eyes, your visual world immediately makes sense. This is achieved by some process by which online visual signals are matched to stored visual representations, and attest to the extraordinary capacity of visual memory. Information that enters the brain through the eyes is stored and remembered in terms of visual representations – in the form of images and sequences of images – or recoded and stored by the brain in terms of verbal or categorical representations. This multiple-coding principle of visual memory is part of the explanation why long-term visual memory generally outperforms other forms of memory. Visual memory recruits many of the brain areas that are involved in online perception, suggesting that the processes of visual perception and visual memory are closely interwoven.

Human memory is not a single mental faculty or cognitive system; rather the cognitive processes which we collectively call memory are composed of a number of independent and specialized cognitive systems that encode and store information in different formats. The various taxonomies of human memory agree on two main distinctions: First, memory may be explicit, or declarative, in the sense that personal knowledge and previous experiences are consciously recollected or recognized, or memory may be implicit, or nondeclarative, in the sense of being expressed indirectly in behavior without accompanying conscious recollection of previous learning episodes (Schacter et al., 2000). Obviously, in most situations, including those of the experimental laboratory, memory systems are activated in parallel, and the resulting performance is supported by several memory systems (Tulving, 2002). It is a challenging task for memory researchers to delineate the contribution of the various memory systems.

Second, a distinction is drawn between short-term memory, called immediate memory by early memory researchers, which is the seat of consciousness and active processing and is able to store limited quantities of information for limited periods of time, and long-term memory, which stores unlimited amounts of information for unlimited periods of time. This distinction, associated with the so-called 'modal model' of memory, is generally, though not universally, accepted among memory researchers (Jonides et al., 2008), however, it is also accepted that the border between short- and long-term memories is diffuse, and that short-term memory performance may be influenced by long-term memory representations.

The concept of *visual memory* has two related meanings: In the most general textbook usage, visual memory refers to the storage of information transmitted through the visual system. According to this definition it is a form of memory, which may be compared with memory for information transmitted through other sensory systems such as auditory, tactile, or olfactory memory. The type of information that is processed (colors, music, smells) and which cannot be translated between modalities captures important characteristics of modality-specific memories. However, this 'channel of communication' definition of visual memory misses the point that vision is a gate to many memory systems, and conversely that information in different sensory channels may be processed by the same amodal memory system. In a more restricted usage, visual memory refers to a code by which visual perceptions are inscribed and retrieved from memory in the form of images or sequences of images. According to this definition, visual memory is not a separate memory system but a form of representation of information that is processed by different memory systems. This definition also acknowledges that the channel of communication does not specify the memory format; what is viewed by the eye may be stored amodally, e.g., in memory systems that rely on verbal codes.

With these distinctions in mind, the article first discusses the relationship between visual perception and visual memory; this section is followed by two sections devoted to visual short-term and long-term memory, respectively, with the contributions of explicit and implicit memory discussed within each section, and the article ends with a discussion of the empirical evidence for the existence of visual memory codes.

Visual Perception and Memory

Perhaps the most direct expression of visual memory is the perceptual process itself, in the recognition of colors, textures, shapes, objects, and visual scenes. This is achieved by some process by which online information from the visual system is matched to stored descriptions. Perceptual recognition is immediate, representing a fast, automatic and implicit (nonconscious) process, and it precedes semantic and episodic memory retrieval, which deals with the identification of particular, familiar objects and visual scenes. The vast collection of stored representations that allow perceptual recognition is at least partly associated with a separate memory system, called the *perceptual representation system* (PRS). It is believed to consist of several subsystems, one of which is a structural description system, which stores descriptions of coherent or meaningful objects. Object recognition is further influenced by the process of *priming*, which is a largely nonconscious or implicit memory system belonging to the PRS (Schacter et al., 2000). In priming, recognition of objects is speeded up by previous presentation of related information and slowed down by previous presentation of conflicting information. These influences may cover extended time periods, well into the long-term memory domain.

The close link between visual perception and visual memory is further illustrated by the observation that certain forms of perceptual deficits due to local brain lesions appear to affect memory as well. For example, persons who lose their ability to see colors owing to bilateral lesions of a region of the occipital lobe known as V4 usually also lose their ability to remember or imagine colors (Sacks, 1995).

Visual Short-Term Memory

Most current treatments of visual short-term memory are based on the theory of *working memory* proposed 40 years ago by Baddeley and Hitch (1974), later developed in a very influential book by Baddeley (1986) and in several subsequent papers (Baddeley, 2000, 2012). According to this theory short-term memory is not a simple mechanism for passive storage of information, rather it is a coordinated set of mechanisms that combine incoming information from sensory systems with information retrieved from long-term memory, and consists of a central executive operating with the assistance of two domain specific support systems or buffers, dealing with visual–spatial and verbal information, respectively, and one multimodal system, the episodic buffer. Broadly speaking, the concept of *visual working memory* refers to the short-term memory system, which stores information that enters the brain through the eye. But as already noted, the definition is too broad since visual information such as written words or pictures of naturalistic scenes is easily recoded and stored in verbal memory systems. A more restricted definition of visual working memory is *the maintenance and manipulation of information represented as visual codes*. Since, with complex, meaningful visual stimuli memory performance may by supported by visual and verbal working memory systems operating in concert, much of the research in visual working memory has aimed at isolating the visual component of memory.

The Visual–Spatial Sketchpad

The support system referred to as the visual–spatial sketchpad is not a purely visual processing mechanism, but thought to combine information from visual, tactile, and haptic sensory channels. To a first approximation the visual–spatial sketchpad can be compared with the phenomenon of visual imagery. Visual imagery is the ability to produce 'inner' images of previously seen persons, objects, and geographical scenes, and to produce images of scenes that are simply imagined. Visual mental imagery tasks require subjects to retrieve information from long-term memory or to maintain visual information that has recently been viewed, and to perform cognitive operations on, or make judgments about, this information. The purely visual nature of visual imagery is supported by experiments showing that cognitive operations on visual mental images are governed by the same laws as similar operations performed on online visual images, and that visual imagery recruits many of the brain regions involved in online perception, even perhaps including some of the earliest brain regions in the visual process. This process is quite similar to the task of the visual–spatial sketchpad, and there is evidence that visual memory and imagery activate a number of common brain regions (Slotnick et al., 2012). However, whereas visual imagery is conceived as a conscious process of image generation, maintenance in visual working memory is not conceived as a conscious process in the same sense. Differences between visual imagery and the visual–spatial sketchpad are also suggested by the finding that visual imagery is disrupted by task-irrelevant visual noise whereas maintenance in visual working memory is not disrupted by visual noise (Repovs and Baddeley, 2006). Thus, despite similarities, visual imagery and the visual–spatial sketchpad are not identical.

Capacity Limitation of Visual Working Memory

The capacity of visual working memory depends upon several factors, such as the type of information tested, the test procedure employed, the time allowed for memory encoding, and the discriminability of the items in the visual display. There are individual differences in working memory capacity and there are age effects. Visual working memory performance in the adult population starts to decline around 60–65 years of age, and decreases steadily toward older age, a trend it shares with most memory tasks involving explicit but not implicit memory (Nilsson, 2003).

Until quite recently, most research on visual working memory has been concerned with the spatial aspect of visual displays and comparatively little was known about memory for the other properties of visual objects and visual scenes, such as their color, texture, and orientation. Experiments investigating the object property aspect of visual working memory suggest that visual object working memory is a unitary mechanism, with a capacity limitation that is fairly independent upon object properties and complexity. To a first approximation, visual working memory may be conceived as storing integrated objects, thus when remembering objects and their properties, it does not matter if they have different colors and orientations or if they share these features. The capacity limitation is four objects; when the number of objects exceeds this limit, memory suffers (Awh et al., 2007). This does not mean that the visual working memory capacity is completely unaffected by stimulus complexity. While the number *four* pops up in most experiments, it is clear that several stimulus and encoding parameters determine the capacity of the visual working memory. For example, if object complexity is high and encoding time is low, the estimated visual working memory capacity decreases, but if object complexity is high and there is unlimited encoding time, capacity increases but appears to not exceed the magical number four.

Fractionation of Visual Working Memory

Recent experiments indicate that visual working memory may be composed of additional subsystems. It is now realized that there is one cognitive subsystem that is partly specialized for processing objects and object properties such as color, orientation, and shape, and a second cognitive system that is specialized for processing the spatial characteristics of visual displays (Repovs and Baddeley, 2006).

A powerful experimental strategy in studying the independence or interaction between cognitive processing systems, are the so-called *dual-task experiments* where participants are

required to carry out two tasks simultaneously. For example, participants may have to remember a previously presented visual pattern while counting backwards or making a spatial judgment. The results of such experimental manipulations provided strong evidence for separate verbal and visual memory systems, showing that the performance on visual working memory tasks is not impaired by a parallel verbal task but it is impaired by a parallel visual task, with complementary pattern found for verbal memory tasks. Concurrent visual processing tasks compete for processing resources whereas verbal and visual tasks are processed independently. A similar pattern of interference is found between visual and spatial tasks, both handled by the visual–spatial sketchpad: Visual short-term memory tasks are more strongly disrupted by visual than spatial interference, and spatial memory tasks are simultaneously more strongly disrupted by spatial than visual interference. This double dissociation strongly supports a fractionation of visual short-term memory into separate, parallel, limited-capacity, visual and spatial components (Klauer and Zaho, 2004).

Implicit Visual Short-Term Memory

While the concept of visual working memory is largely based on studies of explicit memory where participants are requested to remember specific stimulus items, implicit influences on visual working memory through perceptual priming is recognized (Baddeley, 2010). Further experimental evidence for an implicit component of visual short-term memory comes from a parallel line of research on so-called *perceptual memory* (Magnussen, 2000). In classical visual working memory tasks, participants are required to consciously remember the stimuli to be compared and the difference between the patterns is easily detected in simultaneous displays. In a typical experiment one object in the display may change in color, orientation, or shape, and across experimental conditions the number of objects in the display and/or the number of object features is varied. This approach is governed by what some cognitive psychologists call a *storehouse* metaphor – how much is retained in memory? Perceptual memory research, on the other hand, is governed by a *correspondence* metaphor, investigating the fidelity of memory. How well are the details of the original display retained, and what distortions of color, texture, and orientation are observed? In these experiments the memory of elementary attributes of visual images – size, orientation, movement – is measured using psychophysical discrimination tasks where participants are requested to decide, or guess, if a test pattern has a higher or lower value than a previously shown reference pattern on the stimulus dimension is question, and a discrimination threshold is determined, usually representing the value of 75% correct guessing. The results from these experiments show, somewhat surprisingly, that information about such elementary attributes is not degraded or distorted, but maintained with a fidelity of the sensory image during intervals up to 2 or 3 min. The storage is impaired by a concurrent processing task along the same dimension, but not by a concurrent task along another dimension, and there is evidence that at least three stimulus dimensions may be stored in parallel. Thus the pattern of interference mimics the interference pattern observed in the more traditional visual working memory tasks. However, the performance on this task does not require conscious recollection or recognition, the differences that are discriminated in memory are so small that they escape any verbal labeling. The high-fidelity memory performance depends upon the forced choice technique in which the participants often feel that they are just guessing, but also that they are guessing correctly. From such observations it was concluded that the memory performance in such delayed discrimination experiments was based on an implicit type of memory, rather than on explicit memory. This low-level memory system may be a part of the visual working memory system or form a parallel implicit memory system associated with the PRS. Its role in visual memory is not known but it might store information about visual features that helps building permanent object representations (Magnussen et al., 2010).

Visual Long-Term Memory

Visual Representation in Episodic and Semantic Memory

The picture in the morning paper is not just a sidewalk cafe, it is the Deux Magots in Paris, and the person in the front row is not just a female figure, it is the movie star, *la grande dame* of French movies, Catherine Deneuve. The conscious recognition of particulars is a visual expression of semantic memory – a memory system that stores information about general facts. And if you are a Parisian or happened to be a lucky tourist, you might also remember seeing Catherine Deneuve walking by as you were sitting outside the very same cafe, and you might remember her looks at that particular day. This production of a memory image to the 'inner eye' is a visual representation of episodic memory, a memory system that stores information about personal facts and episodes. Semantic and episodic memory represent declarative or explicit forms of memory. Both personal observation and experimental research testify to the human capacity for visual episodic memory.

The experimental investigation of visual long-term memory is closely associated with the study of pictorial memory. In a series of classical studies in cognitive psychology (Standing, 1973) participants viewed large numbers of black-and-white and color slides of natural scenes, objects, persons, interiors, and landscapes, and memory was later probed by presenting pairs of slides containing one previously seen and one novel picture and asking the participants to pick from each pair the picture they saw in the study phase. Human participants are amazingly good at this task. With a learning set of 2500 pictures the score was on average 90% correct after a 36 h memory interval, and with a learning set of 10 000 pictures the score was 84% correct in the test trials. This easily outperforms the memory for words tested with similar methods. The excellent recollection of pictures and visual scenes has been explained in terms of the dual coding theory, which distinguishes between visual and verbal memory codes (Paivio, 1995). Picture memory has an advantage because pictures are effectively coded in both memory systems whereas words are coded primarily, but not exclusively, in verbal systems. The effectiveness of dual coding is illustrated by memory enhancing techniques, e.g., in the method of loci where items to be remembered are attached to places in a visualized familiar

environment and later retrieved by mentally traveling the same path in memory. The distinction between visual and verbal coding systems is also a central part of theory of working memory.

Implicit Visual Long-Term Memory?

What is remembered in the experiments of Standing (1973) and subsequent studies of pictorial long-term memory? Is it really possible to remember that many pictures in detail or is the memory performance based on 'gist' memory? Gist memory is the general meaning of the scene that is independent of explicit knowledge of what the scene contain. In addition, the method that is used in most of these studies, the two-alternative forced choice technique, is open to guessing and implicit memory influences. Thus, the impressive memory performance in the classical experiments may be result of gist memory and/or heavily influenced by implicit memory. Rensik (2000) proposed a theory of visual scene perception in terms of three systems: A low-level vision system that analyzes the basic features of visual stimuli, a second system that of focused attention that provides information about particular attended objects, and a third system that takes care of scene schema, providing information about layout and gist. So, in harmony with the view of Tulving (2002) pictorial long-term memory is supported by both explicit and implicit memory systems.

There is now strong evidence for the contribution of implicit memory to long-term pictorial memory. In a study by Vogt and Magnussen (2007) participants studied 400 color photographs of front doors, each picture presented for 5 s, and were later tested for the memory of the pictures across a period of nine days. There were two conditions, original pictures and doctored pictures where minor details were removed, details that were largely undetected by the participants (see **Figure 1**). Eliminating the influence of gist – all pictures were pictures of doors – the results of the experiment, in conjunction with the results of the classic Standing (1973) study, demonstrated the importance of both visual details and of gist memory: A comparison of the results for the original pictures with the memory performance of the participants in the comparable condition of the original Standing (1973) experiment, showed that by eliminating pictorial diversity memory, long-term memory performance dropped by 10–15%, and an additional drop in memory performance by 15% was observed in the 'doors' experiment when the unnoticed details were removed in the 'doors' experiments (see **Figure 1**). The results of a series of studies with large number of naturalistic pictures (Brady et al., 2008) further argue that details are important in long-term visual memory. Even after viewing thousands of pictures in different categories, and with many exemplars in each category, the subsequent memory performance was very high. In general, the results of long-term visual memory studies tend to support the multiple-system theory of Rensik (2000), which acknowledges contributions from both explicit and implicit memory systems to long-term visual memory.

The Evidence for Visual Memory Codes

The necessity for postulating visual codes has been questioned by cognitive psychologists who favor a unitary memory system based on propositional, languagelike codes. As an illustration, studies of memory expertise have shown that the memory of chess masters is vastly superior to that of ordinary players for real game positions, but not for random positions of chess pieces on the board (De Beni et al., 2007). The expertise memory is explained by the fact that masters have a long-term storage of a large number of visual 'chunks', where a chunk is a constellation of actual game positions involving a few pieces, and the estimated number chunks is about 50 000, which is comparable to the number of words commanded by

Figure 1 Visual memory for naturalistic pictures when the gist memory is eliminated. Participants viewed 400 color photographs of front doors and were later tested for the memory of the doors, at each session 100 studied doors were paired with 100 novel doors and the participant decided which of the doors had been previously shown. Results (right-hand panel) are shown for original pictures (left-hand panel, upper row) and pictures where minor details were removed (left-hand panel, lower row). Single point plots the result of Standing (1973), who had participants study a comparable number of random naturalistic pictures. Eliminating 'gist' memory indicates a drop in memory performance of about 15%, and eliminating minor details in the picture leads to an additional 15% drop in memory performance. The results strongly support a multiple-component theory of visual memory. Reprinted from Vogt, S.E., Magnussen, S., 2007. Long-term memory for 400 pictures on a common theme. Experimental Psychology 54, 298–303.

persons with a college education. Obviously, such chunks may be effectively represented either in terms of image codes or in terms of propositions or in both.

However, it is now widely recognized that visual memory, at least partly, depends upon visual memory codes, and some of the research cited above provides strong evidence that the brain employs such codes: The implicit memory representations that are responsible for the immediate perceptual recognition of the visual world cannot possibly be understood in terms of verbal or categorical codes. Also, the studies of perceptual memory provide strong evidence for pure visual memory codes, as the memory performance on these tasks escapes any verbal or categorical representation – the only way to perform these tasks is to rely on purely visual representations. The results of dual-task experiments provide additional evidence for separate visual and verbal representations, at least in short-term memory range. In long-term memory, the extraordinary retention of naturalistic pictures and the results of the experiments on the importance of visual details are difficult to interpret in terms of verbal or categorical representation. Additional arguments may be summarized under four headings.

Nonhuman Primates Have Detailed Visual Memories

A large number of experiments with monkeys have shown that these animals can learn to discriminate between large numbers of complex abstract fractal or snow-flake type visual patterns, store these in long-term memory, and utilize the information in single-trial short-term memory tasks. Few, if any scientists have claimed elaborate propositional representation in monkeys.

Perceptual Learning and High-Precision Storage of Sensory Information

In one famous experiment, an eidetic subject was able to identify the three dimensional figure hidden in random-dot stereograms when the left and right-eye patterns were viewed on different days (Stromeyer and Psotka, 1970). Such high-fidelity images cannot reasonably be stored in terms of propositions. Long-term memory changes in the form of perceptual learning are also well established. Subjects get better at performing fine discriminations between orientations or textures across large number of training sessions. The learning is specific for the training conditions and does not transfer to other conditions; for example, when subjects are trained in discriminating visual textures in one part of the visual field, the training effect does not transfer to other parts of the visual field (De Beni et al., 2007). Thus, at least some forms of visual memory must be due to local neural changes closely associated with the perceptual process itself.

Dissociation between Visual Memory and Other Forms of Memory

Lesions of the brain, which disturb semantic and episodic memory may leave the perceptual recognition process intact. The patient's perception of the world is normal but he or she does not remember seeing these objects or persons before. Recognition memory may, however, be demonstrated though perceptual priming: If the patient is shown a drawing of an object and at a later time is shown the same drawing again, there is a gain in the time required to identify and name drawings that were previously seen compared with novel drawings, and the gain is comparable for amnesic and normal subjects. If, on the other hand, the link between visual memory representations and online perception is disrupted, amodal (verbal) episodic and semantic memory may be intact but the person can no longer recognize what he or she sees. In the neuropsychological syndrome of *visual agnosia* the patient sees but the visual world is meaningless. There may be nothing wrong with the perceptual process per se, and the person navigates safely in the geographic environment and may even copy diagrams and drawings. However, there is no visual recognition and no visual memory, although other forms of working memory (and long-term memory) may be completely intact, but the information, which comes from vision is meaningless (Farah, 1990).

Visual Processing Areas of the Brain Are Recruited in Memory Tasks

Modern brain imaging techniques such as functional magnetic resonance imaging that allow fairly local and precise brain activity patterns to be mapped during the execution of cognitive tasks, would appear to offer a unique possibility of isolating the visual versus verbal components of working memory. But isolation of specialized memory systems is not a simple and straightforward procedure, both because cognitive tasks activate many brain systems concerned with perception, attention, and memory, and because most neural networks in the brain probably perform many processing tasks in parallel. Even if the performance on a specific visual memory task is not assisted by verbal memory, the simple fact that we identify a recognizable pattern that can be verbally classified and later remembered implies activation of verbal memory processes. Imaging studies have demonstrated distinct areas localized to the occipital and temporal lobes of the brain, specialized for processing particular classes of stimuli such as objects, scenes, and human faces (Haxby et al., 2004). These regions are activated in visual memory tasks with these classes of stimuli but not in verbal memory tasks, suggesting that at least certain kinds of information is represented as visual codes. Otherwise, imaging of memory processes in the human brain has shown that there are no regions specialized for storing or maintaining memories (D'Esposito, 2007). Memory involves widely distributed networks and all major regions of the cerebral cortex have been implicated in the various forms of memory. Since visual memory is a form of representation, a code rather than a system, one would expect it to share processing space with other cognitive memory systems, in addition to activation of the regions that are specific for the processing of visual information. Memory researchers generally agree that memories may involve many of the neural ensembles that were involved in the processing of the information in the first place, what is debated is how far down the processing hierarchy recruitment extends. Some brain imaging studies claim that the primary visual cortex (area V1), i.e., the very earliest level of sensory analysis receiving direct input from the eye, is activated in visual memory tasks (Harrison and Tong, 2009). The role of these early regions in short-term and long-term visual memory is a challenge for future research. They may be activated in visual recognition and delayed

discrimination tasks, but it is less likely that they are activated in memory tasks involving visual imagery. Since memory images are normally much less vivid and detailed than perceptual images, and memory is rarely confused with perception, they must activate at least partly different neural circuits (Slotnick et al., 2012).

Looking Ahead

One of the major advances of modern cognitive science is the idea that the human mind is functionally organized in terms of multiple independent processing systems, each system devoted to a particular cognitive task. In vision research, the idea of parallel, specialized processing systems was quickly accepted following the pioneering studies of the Nobel laureates David Hubel and Torstein Wiesel (1959), which showed that there were specialized neurons – in cognitive research termed channels – for processing features of the visual stimulus, such as color, orientation, size, and motion. The idea of modular organization of memory has had a slower progress. The current concept of visual memory identifies several memory systems as detailed above, and the distinctions between implicit and explicit memory systems, and the multiple-component working memory model, have been very successful in organizing the vast cognitive research literature. However, current neuroscience does not provide evidence for such a modular organization of memory, at least not if modules are defined in terms of localized brain processes. In the case of visual memory, an alternative view would be a model of memory that parallels the visual perceptual processing strategy of the brain, with the low- to higher-order specialization of the processing of visual features, objects, and scenes, and where different sensory areas are recruited depending upon the specific memory task.

Modern research confirms that visual memory is superior to other forms of memory, being able to store vast amounts of information in terms of pictures or natural scenes. Visual memory, in the general definition of memory for information transmitted through the visual system, partly depends on information stored in terms of visual representations, and partly on information stored in terms of verbal or categorical representations. The extremely good retention of visual information of pictures and geographical scenes is likely to be the result of the multiple-systems operation of visual memory. It is the task of future research to specify the relative contributions of the different memory systems to the short-term and long-term visual memory performance, and to decide if the concept of memory systems is indeed a fruitful one.

This article is reproduced from the previous edition, volume 24, pp. 16266–16269, © 2001, Elsevier Ltd.

Abstract

This article is an overview of visual methods in the social sciences, with an emphasis on sociology. The article notes that, relative to other methods, visual methods are underdeveloped in the social sciences. It details forms of visual methods, from empirical to semiotic. Particular attention is paid to the use of photographs in the research process. The article also discusses problems in visual methods, including ethics and matters of technology and representation. Finally, it discusses issues specific to the publication and other dissemation of visual research in the social sciences.

Visual methods, relative to other methods, are underdeveloped in the social sciences. The probable explanation is that social science reasoning generally relies on the analysis of aggregate data, and photography and other visual methods locate their attention on the particular. Thus, it requires a reversal of typical social science reasoning to generalize from the particular, especially when the particular is a visual image.

The nature of visual evidence is also problematical for social science. Photographic (film or video) images appear to represent the world 'objectively,' that is, without interpretation. At the same time, it is recognized that photographs are socially and technically constructed, thus embodying points of view and interpretive influences. The tension between the competing qualities of objectivity and subjectivity influence the use of visual images in the social sciences.

Forms of Visual Methods

Empirical Evidence

Photographs (or photos linked together in film or video) are the most common form of visual sociology. The most common use of visual images is to catalog aspects of material culture or social interaction (see Collier, 1967), which was a common aspect of articles published in the first issues of the *American Journal of Sociology* (see Stassz, 1979). In the first 20 volumes of the *American Journal of Sociology*, until 1916, sociologists used photographs to make arguments about the character of rural and urban life; the working conditions in offices and factories, and living conditions in industrializing cities. As sociology sought a more scientific posture, the visual research method (which was not well developed in these early examples) was largely abandoned.

Anthropologists, working in the first decades of the twentieth century, also used photography extensively (Edwards, 1992). Anthropology's primary mission during its early eras was to document and classify human groups. Photography's ability to gather a large amount of information in a single document made it an important data-gathering method. As anthropology abandoned paradigms based on the taxonomic organization of racial classifications, photography became less important as a research method.

The full development of photography as part of ethnographic analysis is generally attributed to Gregory Bateson and Margaret Mead's (1942) study of Balinese culture. In this project, the researchers used 759 photographs (selected from more than 25 000 made during their fieldwork) to support and develop ethnographic observations and analysis. Bateson and Mead used sequences of photographs to show how the Balinese performed social rituals or engaged in routine behavior. These images typically record the unfolding of events, and thus are similar to short movie clips. The researchers also used images to survey material culture such as dwellings and agricultural techniques. This promising expansion and redefinition of visual anthropology has been followed by contemporary examples such as Danforth and Tsiaras' study of death rituals of Greek villagers (1982), and several other examples in sociology and anthropology.

Howard Becker was the first modern sociologist to suggest a link between photography and sociology (1974). Much of Backer's argument referred to the ability of photographs to record the world as observed. For example, Becker noted that photography and sociology, since their inception, had both been concerned with the critical examination of society. Becker noted that the early twentieth century photographers, such as Lewis Hine and Jacob Riis, were concerned with topics such as urbanization and industrialization, the exploitation of labor, and the conditions of immigrants, all of central concern to sociologists. Becker suggests that a modern visual sociology should emerge from documentary practice engaged with a sociological theory, and the sociological use of visual data developed in the context of common concerns with validity, reliability, and sampling. Becker's article, reprinted in several anthologies, is credited with the rebirth of visual sociology in the US.

In the meantime, sociologists have used photographs as evidence in the study of social change (Rieger, 1996), in sociological classification of farmsteads (Harper, 1997), and other topics that reflect conventional sociological research. Visual ethnography, however, remains a relatively small movement within the field methods tradition in sociology and anthropology.

Photos as Cultural Narratives

Anthropologists have used film and video (and, to a lesser extent, the 'photo essay') to communicate typical events of a cultural scene. This tradition is largely attributed to Robert

Flaherty's seminal ethnographic film, *Nanook of the North*, completed during the 1920s (see Rotha, 1980). The resulting film tradition in anthropology has both embraced and challenged the capacity of visual narrative format to communicate cultural information. Nevertheless, the use of film (and photography) to tell 'cultural stories' remains a viable part of visual anthropology, and constitutes the single most influential demonstration of visual methods in social research. In anthropology, ethnographic films are presented at professional meetings, scholarly film festivals, and as a part of normal pedagogy.

Photographs in the Research Process

Collier (1967) first described how researchers may employ photographs to elicit cultural information. The process, now referred to as 'photo-elicitation,' uses images to stimulate culturally relevant reflections in interviews. Researchers may take the photos prior to the interview, or the photographs may be from a personal collection or professional archive. Photo-elicitation has become a common method in visual sociology, used in a wide range of studies, including public responses to social problems (Faccioli and Zuccheri, 1998), cultural definitions of an urban neighborhood (van der Does et al., 1992), the 'working knowledge' of a rural artisan (Harper, 1987), and ethnic recognition among Asian immigrants (Gold, 1991). The promise of photo-elicitation lies in the understanding of how photographs communicate different meanings to the researcher and the subjects; thus the images become a basis of interviewing that explores the taken-for-granted assumptions of both researcher and subject.

Social science film-makers have integrated imagery into research in a different manner. Beginning in the early 1970s, anthropologists have taught cultural informants to use film and video cameras in order to make films that tell cultural stories from the vantage point of the informant. The first example of this method was Sol Worth and John Adair's research among the Navajo, which resulted in seven films made by native informants (described in Worth and Adair, 1972). With the advent of easy to use video cameras, native-produced visual ethnography has become more common. While controversy continues to surround the redefinition of theoretical authority that native-produced films challenge, most visually oriented social scientists find the native-produced film or video a viable source of ethnographic information.

Problems in Visual Methods

Ethics

There are at least three aspects to the question of ethics and visual methods in research. The first concerns the matter of anonymity; the second concerns the matter of informed consent; and the third represents the burden of 'telling the visual truth.' These three issues are inter-related.

Because social science is generally concerned with the patterns of social behavior, individuals are represented by words, or more commonly, by responses they have made to a questionnaire. Thus the identity of individuals are protected. The protection of the privacy of subjects is, indeed, codified in the ethical canons of the social science disciplines. In the case of visual research, however, it is often impossible to protect the privacy of subjects. All discussion of ethics and visual methods rests on this fundamental fact; the photograph produces a likeness which is often identifiable.

Visual researchers thus face a more pronounced problem of informed consent. Subjects must be made aware of implications of publishing their likeness in social science research, and agreement to participate should be made in writing and prior to the research.

The matter of ethics in visual research is unique among research methods for one final reason. Because it is often possible to identify subjects in research images, visual researchers must be absolutely certain that these images 'tell the truth.' Visually oriented social scientists recognize that it is unethical to alter images to change their meaning, or to present an image that connotes a reality that was not consistent with the understood reality of a situation. Most visual researchers feel that the ethical considerations of visual research most separates it from that of their peers.

Technology

Like all social science methods, visual research depends upon technology. Like all technologies, visual technology makes it possible to record some types of information, but not others. Steiger (1995) detailed how specific cameras, lenses, film types, and camera settings create different kinds of filmic statements, which, in turn, make possible different types of sociological thinking. The specific connection between 'technologies of seeing' (whether relating to photography, film, video, or virtual reality) and social ideas remains an area of enormous potential and scant attention. Steiger's article raises the important point that to be a skilled researcher using visual methods is to master cameras, video and film cameras, and possibly photo printing. Now that many of these technologies have an electronic dimension, skilled visual researchers also need to become adept at software that catalogs visual images, that allows for the improved presentation of images, and that facilitates the production and distribution of images.

New methodologies, such as computer-based multimedia, the World Wide Web, CD publication, and virtual reality, all offer possibilities for the development of innovative visual methods. Each offers an approach for recording, analyzing, and participating in the visual dimensions of society. The future of visual methods in social research will depend, to a large extent, on how well these new technologies are integrated into social science methods and thinking.

Publication: Organizational Basis

In the past two decades, visual research in anthropology and sociology has been institutionalized in intellectual organizations such as the Society for Visual Anthropology, a part of the American Anthropological Association, and the International Visual Sociology Association, an independent scholarly organization with ties to several academic disciplines. Publication of visual methods requires special consideration, and the

journals such as *Visual Anthropology* and *Visual Sociology* feature the presentation of images. The full development of visual methods in social research will require that the mainstream journals and books accept the publication of images as a normal part of social science research, no different than the publication of tables or graphs.

Visual Perception, Neural Basis of

Oliver Braddick, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Following active selection of the input by eye movements, visual perception requires sequential transformations of neural signals, in the retina, area V1, and extrastriate cortex. These transformations create patterns of activity that represent the information needed for recognition, location, and guidance of actions. These representations rest on population coding, in which single neurons carry univariant information, and each neuron acts as a labeled line. Each cortical neuron has a receptive field structure that makes it a tuned filter for properties such as contour orientation. Grouping processes create representations of structure, which serve as the basis, via the ventral cortical stream, for recognition of objects, faces, and scenes in specialized temporal lobe areas. In parallel, the dorsal stream to the parietal lobe creates spatial representations in various frames of reference appropriate for the control of actions. The binding problem – how different aspects of visual information are related to a common object – is important but not yet well understood. Psychophysical thresholds can be related to signals in noise, in specific populations of cortical neurons. Visual cortical activity is not determined solely by bottom-up processing but is subject to central modulation by attention and task demands. The visual system is also plastic and its connectivity can be modified by experience. Possible relations between visual awareness and neural activity are discussed.

Structure of the Visual Pathway

Visual perception is an interactive process in which eye movements are actively used to select the patterns of light entering the eyes. These patterns of light energy are encoded into neural signals in the retina of the eye, and these signals are then transformed as they pass through the neural network of the retina and are transmitted through a series of interconnected brain areas. These transformations create patterns of neural activity that represent the visual information needed for recognizing objects, people, and events; for locating ourselves in the environment; and for guiding actions. We concentrate here on the relatively early stages of this process, often referred to as 'visual perception' but it should be recognized that there are no clear cut boundaries between the brain processes underlying perception and those, sometimes called 'cognitive,' which work with visual information to direct attention, make decisions, retain and access visual memories, and control our actions.

The neural encoding of the visual scene begins in the photoreceptor cells (rods and cones) in the retina, which signal the local light intensity falling on each receptor by their levels of electrical polarization. A network of horizontal, bipolar, and amacrine cells connect these receptors to the retinal ganglion cells. The photoreceptors and ganglion cells are not uniformly distributed across the retina, but are much more densely packed in the central region (the fovea). The closely packed cone receptors in the fovea provide spatially fine-grained information about the pattern of light and dark, giving the high acuity needed for detail vision in daylight vision, and the number of ganglion cells (equivalent to one ganglion cell per cone receptor in the central fovea), ensures that this fine spatial grain is preserved in the information sent to the brain. Thus our sense of a richly detailed visual world is in fact provided by a relatively small high-resolution patch in the fovea, which continually moves around through eye movements to flesh out the coarse layout provided by the low-resolution vision of the peripheral retina.

At low light levels, the more sensitive rod photoreceptors take over from the cones: while rods are 20 times as numerous as the cones, they feed a much smaller number of ganglion cells. These cells pool the rod signals to enable detection of faint lights, at the expense of providing only a coarse picture of the visual scene.

The axons of the ganglion cells form the fibers of the optic nerve, and so the signals that they carry constitute the information that the eye sends to the brain. The nature of this information is discussed in the Section Representation of Spatial Pattern and Shape. At the optic chiasm, these fibers are routed so that signals from the two eyes can be transmitted to each side of the brain, making it possible to integrate binocular information at a higher level.

The lateral geniculate nucleus (LGN) of the thalamus provides a relay station where visual signals can be modulated, but the first major reorganization of the signals from the retina occurs when they arrive in the occipital lobe of the cerebral cortex (*see* Cerebral Cortex and Occipital Lobe (Visual Cortex): Functional Aspects). The primary receiving area, at the posterior pole of the brain, is known as striate cortex, or cortical area V1. It is surrounded by a series of extrastriate visual areas. These areas can be distinguished both by specializations of function (see Section The Hierarchy of Multiple Visual Areas) and by the fact that many of them form distinct, ordered maps of the visual field ('retinotopic' maps). Area V2 receives much of the input from V1, and sends information on to areas V3, V4, and V5. Pathways through these and other visual areas send information to the temporal and parietal lobes of the brain, and are considered to provide a hierarchy of visual processes of increasing complexity.

Within each cortical area, most connections between neurons are quite local. However, information is passed from one cortical area to another in fiber tracts, in an orderly way. Specific layers of the cortex receive input from areas at a lower hierarchical level, while other layers either transmit to higher levels, or receive feedback from higher levels (Bullier, 2004).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.56018-8

Thus, cortical areas are commonly thought of as a set of modules, each performing particular visual computations and passing the results of these computations to other modules.

A minority of fibers in the optic nerve transmit information not to the cerebral cortex, but to midbrain structures, in particular the superior colliculus, which also incorporates a topographic map of the visual field. In lower vertebrates, the corresponding midbrain structures provide the main central visual pathway, but in mammals, certainly in primates, this pathway mainly serves the function of orienting to stimuli by eye movements rather than any complex analysis of the visual image, and probably does not contribute directly to conscious visual perception (see Section The Neural Basis of Visual Awareness). However, there are connections running both ways between this subcortical visual pathway and the much more elaborate cortical network for visual information processing.

Key Concepts of Neural Representation and Their Evolution

Specific Nerve Energies and Place Coding

In developing modern concepts of the neural basis of vision, an early key idea was that messages from the eye to the brain could convey distinct information according to which element of the nervous system carried them. Thomas Young, around 1800, proposed that different colors were represented according to the degree that three forms of 'sensitive filament' in the eye were stimulated, a view that in its essentials, with cone photoreceptors as the sensitive elements, is accepted today. Developments of this idea in the nineteenth century were Lotze's concept that each separate fiber in the optic nerve is associated with a 'local sign' – that is, we can know which point in space stimulated our eyes from which particular fiber is active – and Müller's 'doctrine of specific nerve energies' that the quality of stimulation (e.g., sound versus light) is conveyed by which fibers convey a signal, and not by any distinct quality in the signals themselves. This principle (sometimes called 'place coding' or 'labeled line') is now recognized as fundamental for understanding how visual information is represented within the brain, as well as in the sensory pathways leading to it.

Univariant Coding by Impulse Frequency

The work of Adrian in the 1920s established that sensory information is carried by a series of nerve impulses (action potentials). As the impulses are identical all-or-none events, quantitative variations, for example, in the contrast at edges between light and dark, have to be encoded by the rate at which impulses occur. In principle, more complex statistical properties of the train of impulses could carry rich information, but visual neurophysiology has not yet yielded convincing examples of this. Thus, the activity of a single neuron is univariant – it can encode only a single variable in the visual image. The classic example is in color vision: a particular receptor may respond relatively more strongly to green light than to red light. However, because its response is univariant, its responses to a dim green light and a bright red light are indistinguishable. Thus, to represent even a single variable, within a multidimensional domain such as color, requires information to be combined or compared from two or more neural signals. The modern neuroscience of color vision identifies such comparison in the opponent processing of different cone signals in retinal ganglion cells and higher levels of the visual pathway.

Receptive Fields and Tuned Filters

These principles of neural coding have been particularly applied in considering how the visual system represents spatial information. A concept which developed early was that each visual neuron has a receptive field – a region of the field of view within which light can influence the neuron's activity. Further work showed that receptive fields have internal structure, such that a particular spatial pattern of light and dark within this region is optimal for activating a given neuron. This led to the idea that neurons could be 'feature detectors,' signaling the presence of a specific pattern element, such as a small black moving spot that might be a fly in the visual field of a frog. However, in the mammalian brain at least, it currently seems unlikely that any single neuron on its own can provide such a signal; in all cases that have been investigated, the distribution of activity across some population of neurons would be needed to determine reliably the presence of a particular feature or object (Churchland and Sejnowski, 1992). This idea of population coding should not obscure the fact that, in visual brain areas, coding is sparse. That is, for any particular visual stimulus, only a small fraction of the available neurons are active, and so it is appropriate to think of particular subsets of neurons as being involved in representing particular visual attributes.

Neurophysiological studies in the 1960s and 1970s, pioneered by Hubel and Wiesel, concentrated on how populations of neurons in V1 encoded particular visual properties, such as the orientation of an edge. Each neuron was found to be a 'tuned filter,' which responded to a limited range of orientations. The perceived orientation of a contour can then be derived from the peak of activation across a distribution of differently tuned filters. This idea, originating in recordings of single neuron activity, was supported by psychophysical experiments, which showed that the visual system could be selectively adapted (pioneered by Blakemore, Campbell, and others; the method is summarized by Braddick (2010)). For example, intense stimulation by stripes angled at 5° from vertical reduced the ability to detect low contrast stripes at that orientation, and made vertical stripes appear tilted in the opposite direction. These results are what would be expected if the adaptation reduced the sensitivity of a group of neurons (sometimes called an orientation 'channel') tuned to orientations close to the adapting stimulus and so shifted the distribution of activity across the population of tuned neurons. Cortical neurons also act as arrays of tuned filters for other properties, such as direction of motion, and analogous effects of selective adaptation can also be found for these properties.

The arrays of tuned neurons, as well as allowing properties such as contour orientation to be registered, also make it possible to segregate visual information according to these local properties. Common orientation, color, or motion of texture elements makes it possible to segment the scene into distinct objects and surfaces, and to group features which belong to the same object. Such segmentation plays a key role in the organized perception of a visual scene.

The Hierarchy of Multiple Visual Areas

The finding, that neurons in area V1 were tuned to a range of stimulus properties, led to exploration of higher levels of cortical processing. Experiments with macaques, from the mid-1970s onward, showed that there is a multiplicity of distinct visual areas beyond V1 (*see* Occipital Lobe (Visual Cortex): Functional Aspects). As well as progressive transformations through a hierarchy of visual areas, there was found to be parallel processing by areas such as V4 and V5, which receive information from V1 in parallel via separate routes. These areas are specialized, so that, for example, V5 contains a high proportion of neurons tuned to specific directions of motion but few that are wavelength-tuned, while V4 shows the opposite balance (Zeki, 1993). This has led to a picture of functional separation, within the cortex, of representations which emphasize different aspects of visual information and serve distinct purposes.
